Whether the system of regulation by which certain beneficent results have been achieved during the war can be effectively carried out in peace time without the direct management of the liquor business by the State is a question which only experience can decide. The answer will depend, no doubt, in a very large measure on the capacity of the licensed traders to take an intelligent view of their own interests. With the example of America before them—where the intolerable abuses of the American saloon were the chief argument for prohibition—they should be able to appreciate the full force of Lord D'ABERNON'S epigrammatic warning that "the noisy advocates of unrestricted indulgence are the cats-paws of Pussyfoot." And it is equally desirable that the nation should realise the immediate and inevitable results of complying with the demands of these advocates. If we withdraw reasonable restrictions we shall create almost a legitimate demand for unreasonable ones.

## Some Housing Questions.

THE influence which housing conditions exercise upon the incidence, spread, and permanence of disease is so enormous that no apology is needed for recurring notices of the developments now taking place. The housing problem is being dealt with seriously, and upon what is intended to be a scheme of general application, for the first time in this country, and this general application is, perhaps, indicated by the absence of any definition of the class of citizen whose need for accommodation is exercising the community at large. A series of questions has been addressed to Dr. ADDISON by the Council of Rotary Clubs of London, and other inquiries have been directed to this point. Dr. ADDISON, in reply to the Council of Rotary Clubs, said that he had deliberately "and obstinately" refrained from defining "a workman." "A type of house," he said, "is sanctioned, and it is left to the local authorities to use their own common-sense as to who shall occupy the houses." Dr. ADDISON was, however, betrayed into something very like a definition such as he had obstinately declined to give, for he

continued: "A workman is a man who works, and it is immaterial to me whether he works as a bank clerk or a navvy." This indicates at any rate that the honourable term of workman is not to be confined to manual labour, but it does not say with what strictness the new dwellings are to be confined to those who "work." Are they to be denied to the naval or military pensioner debarred by war injuries from work? Is the widow of a man who has saved a little money for her and his family to be excluded from them? Will a worker of any sort, in receipt of wages which fairly might enable him to rent a more expensive house, be made to do so? This last question was actually answered by Dr. ADDISON by saying that rents will be fixed according to the type of house, and cannot be graded according to the proposed tenant's earnings. Where there is competition for the new houses there will be a good field for the exercise of the common-sense with which we are willing to credit the local authority, and for allotting the new habitations to those for whose benefit they were provided. From the health point of view this may be of importance; competition for the houses will promote rivalry in keeping them decent, and once a neighbourhood begins to pride itself upon being clean half the battle of public health is won.

In London the conversion of houses into working-class flats will presumably be the branch of rehousing which will first show tangible results. Such conversion has taken place before, but not on the large scale now contemplated, and the securing of satisfactory health conditions will not always be as easy as the mere conversion itself. To turn a house, built to contain one middle-class family, into three or four self-contained tenements for workmen may dispose of that number of families so far as their lodging at night is concerned, but when streets or rows of houses are thus treated a comparatively crowded area will take the place of one more sparsely populated. The children have to be considered in places where the children of former occupants played in the back garden of the one house belonging to or rented by their parents and gave no cause for anxiety to anyone. We doubt the children of four families living in one house sharing its yard or garden harmoniously. Children will do better in larger playgrounds, where they can find friends adapted to their tastes and have some kind of supervision, official or voluntary, to keep them out of mischief. We hope that in all housing and building schemes the health and enjoyment of the children when out of school will be kept well in view, and recognised as an essential aid to the well-being as well as the happiness of the population. The streets and public roads in urban districts are not proper playgrounds whether for babies or for bigger girls and boys. A public park or playground may accommodate thousands and be an excellent place for holiday time, but at half a mile distance or even less it is of no use for everyday purposes. Small playing areas for the children coming from ten up to a hundred houses, standing open within easy reach, might make it possible to forbid absolutely their enjoyment of the danger of the highway.

The reconstruction of houses into flats should lead to increased housing accommodation more quickly than the construction of new buildings, but it is to the new buildings that the medical man looks for such a solution of the housing troubles as may lead to an actual improvement in public

health conditions. Conversion of large houses into flats is an economical proceeding of itself and should have considerable advantages, because the quality of fabric is higher than may be available in these days. But no choice of site is left, and it is here and in the planning of the arrangements of roads and approaches that we look for the main improvements in the houses of the future. Much of the insanitary horrors of the existing workmen's dwellings has been due to the absence of any prevision in building; but now that housing and town planning are being carried out under the ægis of a Ministry of Health neglect of the real sanitary outlook should not be feared.

### Dearer Milk and Bread.

GREAT and immediate efforts are needed upon the part of all local authorities to protect the population against the hardships arising out of a milk-supply at famine prices. Mr. McCURDY, the Parliamentary Secretary to the Ministry of Food, in a speech delivered at a recent meeting of the Consumers' Council, issued a warning that it is probable that the retail price for milk throughout the country next winter will be at least 1s. a quart, which is an advance of 2d. per quart on last winter's rates. This will mean a heavy burden on the resources of the working-class families and, likely enough, a serious increase in the rate of infant mortality. "We have to make good," Mr. McCURDY concluded, "the wastage of human life that took place during the war. Our baby crop for the years 1914 to 1919 is in danger. We must save it." It is well to remind local authorities of the powers conferred upon them by an order of the Ministry of Food last year. Subject to such conditions as might be laid down by the Food Controller, any local authority could arrange for the supply of milk for children under 5 years of age, and in necessitous cases such milk might be sold at less than cost price, or even supplied free. The dairy farmer, of course, must have a reasonable return, and with the increased cost of production and shortage of hay and roots the price of dairy produce must rise. It is to be hoped that the Government are taking steps to secure auxiliary supplies in the shape of dried milk, which appears to meet the dietary requirements of the infant quite well, and further attention should be given to the possibility of imitating milk by emulsion mixtures containing fat protein and carbohydrate, plus, of course, the vital accessory factors. Lastly, the healthy adult should cut down his accustomed supply of milk, particularly in tea and coffee, and thus place a substantial quantity of milk at the disposal of those who need milk if they are to live. Milk can well be excluded from the healthy grown-up person's diet without the slightest dietetic sacrifice, and all who thus penalise themselves will be rendering the State a great service by foregoing an article of food which belongs essentially to the young.

Less anxiety, perhaps, need be felt in regard to the dearer loaf, as the advance in price is relatively small and the staple constituent of bread—carbohydrate—can be made good by other commonly occurring articles of diet. It may be remembered that, in dealing with the operative bakers' grievances, the Court of Arbitration, having regard to the hours and wages of the workers and the factors governing the cost of production, concluded

that the demands of the operatives, which were reasonable, could be met by slightly raising the cost to the consumer of the 4 lb. and 2 lb. loaf by one halfpenny and one farthing respectively. This advanced price is solely due to the increase in wages conceded to the baker. The new prices are based still on a State subsidy, which provides against a greater rise in the price of the loaf. This subsidy, of course, comes out of the pockets of the tax-payers. The period of the war showed that the general health of the community was not seriously affected by the restrictions placed on bread allowance or by the modifications which were enjoined as to its composition. The shortage of carbohydrate in the form of bread was easily compensated by the supply, amongst other things, of rice and potatoes, and this was done with no harm to anybody.

The adult can deal with such a situation without much inconvenience, but not so the baby. The process of turning pasture into milk involves greater economic interests than are present in the growth of seed and the development of the tuber and cereal. For the latter source of food-supply the home allotments should be kept going, as though the war is over the difficulties of food-supply evidently remain. Intensive home cultivation has proved a great success, and no hindrance should be put in the way of continuing the undoubted assistance which allotments gave to the food resources of the country. Neither should the healthy occupation which the allotment involves be checked. But the problem of milk for children remains, and it can best be met by rigid economy in its use by adults.

### Fees for Public Vaccination.

THE Association of Public Vaccinators of England and Wales has justified its existence in a number of ways. It has done much to promote a high standard of efficiency in the vaccination service; and although primarily concerned with the interests of public vaccinators and the conditions of service, the association has also been active in the defence of vaccination *per se* for many years. A deputation received by Major ASTOR at Whitehall during June stated—not for the first time—a case for improvement as regards fees and conditions of service for public vaccinators, and urgently called for a recision of the Act of 1907 which has been the cause of much neglect of vaccination by substituting a statutory declaration for the certificate of conscientious objection required under Section (2) of the Vaccination Act of 1898. Major ASTOR, in his reply, was by no means unsympathetic, and assured the deputation that he would lay all their points before the President of the Local Government Board, who would give them his most careful consideration. On July 14th the Association addressed a letter to the Minister of Health on the subject of the increase of fees payable to public vaccinators, and Sir ROBERT MORANT replied on July 24th:—

"I am to state that the Minister has it in contemplation to modify the existing Order by raising to 5s. the present minimum fee of 2s. 6d. or 3s. 6d., as the case may be, for primary vaccination performed at the residence of the person."

We congratulate the Association upon its success in obtaining this concession, even though it be not immediate, for contemplation in Government offices may take some time to develop into action.

## Annotations.

"No quid nims."

### HOME "DOCTORING" AND THE SPREAD OF INFECTIOUS DISEASE.

THE medical officer of health for Ealing has recently presented to his public health department an interesting report dealing with a local outbreak of scarlet fever. Of 25 cases in all, 18 were in children attending North Ealing school, 1 attending Drayton school, 1 a private school, and 4 were under school age. The outbreak began in May, two cases being notified in that month, one on May 6th and the other on May 9th. Further cases were notified on June 2nd, 11th, and 12th. To determine the actual source of infection Dr. T. Orr arranged that on June 18th the hands of all the children in the three classes in which scarlet fever had occurred should be examined, but no child was found to show evidence of infectivity. Absentees were followed up and one child was found whose hands were desquamating, and the mother said that the child had had a rash on May 30th. This child was in the same school class as the two cases notified on June 2nd and 12th. On June 21st all cases in the North Ealing area which had been notified during May and June as suffering from measles or German measles were visited, with the result that one child attending North Ealing School, notified as a case of German measles, was found to be desquamating in a manner typical of scarlet fever. On June 23rd and 24th every child in the North Ealing School was examined and three children in classes not previously examined were found to be desquamating, while one child, in a class already examined as far as the hands, was found to be desquamating on the chest. All these children were sent home and visited, when it was found from the mothers that in every case the children had had a rash from two to three weeks previously. Among the absentees who were also visited two other cases of missed scarlet fever were found, making in all eight cases which had been missed, one of these having been notified as German measles. After this a constant daily supervision was kept over all absentees, who were visited at home, their parents being warned in any cases of suspicious illness, with the result that three new cases were discovered at an earlier date than they would otherwise have been. Dr. Orr remarks upon the large number of missed cases, i.e., 8, in comparison with the number of notified cases, 25. The affected school is in excellent sanitary condition, but, continues Dr. Orr—

"I have been remarkably struck on my visits to some of the houses of the children found to be recovering from scarlet fever to find the mothers so full of knowledge as to what the children suffered from, a knowledge which was pitted against mine in discussing the nature of the condition, and which was gleaned ostensibly from some 'Family Physician,' a volume which was handed to me on two occasions to see on what authority they relied."

It is obvious that in such conditions as Dr. Orr describes we have an ideal position for the spread of scarlet fever or any other infectious disease. Scarlet fever is sometimes very easy to diagnose, and sometimes very difficult, or even impossible. An untrained observer, relying upon information gained from such a volume as Dr. Orr mentions, is subjecting the community of his or her residential neighbourhood to a criminal risk.

## ACUTE THYROIDITIS.

To the *Albany Medical Annals* for June Dr. G. E. Beilby has contributed a careful study of a very rare condition—acute thyroiditis. It might be supposed that the proximity of the pharynx, tonsils, and lymphatic structures of the throat would predispose to infections of the thyroid by lymphatic extension. But it has been shown that there is no lymphatic circulation between the structures of the throat, which are so commonly the seat of acute infections, and the thyroid gland. Cases in which infection occurs by way of the lymph vessels seem to be always preceded by infection in the upper trachea or larynx. Infection from the blood-stream appears to be the most frequent cause of inflammation in cases of tumour or hypertrophy of the thyroid, the consequent processes of degeneration lowering the resistance. It is particularly in adenomata undergoing degeneration and containing free blood and necrotic material that infection occurs. The following is an example:—

A married woman, aged 33 years, the mother of three children, was admitted to the Albany Hospital on Jan. 10th, 1919. She first noticed enlargement of the neck four years previously, just after the birth of her youngest child. The enlargement was gradual until about six months ago, since which time it had been more rapid. The pressure of the growth caused discomfort, and at times difficulty in breathing. About three months before admission she had a severe attack of influenza. Before she left her bed her neck began to swell and to be painful, and there was a rise of temperature every day. On New Year's day she had a chill and from that time grew rapidly worse. Her breathing became more difficult and she lost her voice. On admission she was suffering from dyspnoea and dysphagia. She was profoundly septic and in a critical state. There was a large and very tense tumour in the median line of the neck, a little more prominent on the left side. The temperature was 103·5° F. and the pulse 120. Infected thyroid adenoma was diagnosed. Under local anaesthesia the mass was opened and a large amount of purulent fluid, mixed with blood and broken down thyroid tissue, escaped. Free drainage was instituted. Cultures of the fluid yielded a hæmolytic streptococcus. The patient was very ill for two weeks, but eventually was able to leave hospital with a small discharging sinus. This completely healed and she slowly regained weight and strength. She was advised to return later for removal of the adenoma. The adenoma had undergone cystic degeneration and the infection was undoubtedly hæmatogenous and part of the general influenzal infection.

Two other cases are related in which the infection of the thyroid was a direct extension from the throat, which was inflamed. The symptoms of acute thyroiditis vary according as the inflammation of the gland is primary or arises in some lesion previously existing. In the former case there are usually chills, malaise, and headache. Pain is felt in the region of the gland, more pronounced on one side, because the process usually begins in a single lobe, often radiating to the ear and side of the neck, lancinating and greatly aggravated by extension of the head. As a result the attitude may be somewhat characteristic, the head bowed and held very rigid. Local swelling is never noticed as an early or a marked symptom. Dyspnoea and dysphagia are present, the degree depending on the severity of the infection and the extent of gland involved. The voice may be affected; there may be aphonia and an irritative cough with slightly blood-stained expectoration. The diagnosis is usually difficult and the condition is unrecognised for a considerable time because the usual signs of inflammation and suppuration are absent. The gland is surrounded by a closely adherent connective tissue capsule derived from the pretracheal layer of deep cervical fascia. A layer of the capsule also encloses the larynx and

trachea and pharynx and oesophagus. Hence the swelling of the gland produces its first and most marked effect upon the trachea and oesophagus. The cause of the resulting stenosis is usually sought in the throat. But there is a pathognomonic symptom—stony hardness of the gland on palpation. As the condition of the throat renders administration of a general anaesthetic difficult and dangerous, operation should be performed under local anaesthesia. A free opening should be made and drainage established. As little injury as possible should be done to the gland, and no extensive measure, such as partial excision or removal of tumours or cysts, undertaken in the presence of such serious infection.

## THE PLIGHT OF HOSPITALS IN AUSTRIA AND HUNGARY.

AN appeal drawn up by Dr. Hilda Clark, who has recently joined Dr. Hector Munro in Vienna, brings up to date<sup>1</sup> the urgent conditions of want in which the hospitals of Austria and Hungary find themselves. In both these countries, while the standard of professional skill and permanent equipment remains very high, the staff is faced with the impossibility of giving their patients the treatment which they require. In Vienna, where the hospitals are maintained by the State, milk and eggs are only provided for infants under 1 year, as although the cost at which these articles can be obtained in the country is lower at the present rate of exchange than the prices which are paid for them in England, the State is too poor to buy them and other requisites. The hospitals have therefore to carry on without linen, surgical dressings, rubber appliances, drugs, anaesthetics, soap, or disinfectants. Paper clothing and bandages are everywhere in use, better dressings being reserved for very special cases. The shortage of coal and gas has reduced the opportunities of sterilisation far below the limit of safety. In Budapest a sudden crisis in the food position, which up to that time had been better than in Vienna, was produced by the Roumanian occupation. The shortage of hospital requisites, including dressings and drugs, and the limited opportunities of sterilisation were, however, already more acute in the Hungarian capital. Some spread of sepsis and of skin diseases in the general wards and an increased morbidity rate in the maternity wards has so far been one of the results. The lack of anaesthetics has been partially met by the extended use of local anaesthesia, but it is obviously impossible for the whole medical profession to acquire at a moment's notice the skill and experience thus necessitated. The shortage of general anaesthetics and of morphine has been particularly felt in the obstetric clinics. The appeal suggests help in three directions. The first essential is coal, which can presumably be paid for on credit if not in money; secondly, some help with the hospital supplies is urgently needed; and thirdly, assistance to the hospitals and sanatoriums to cope with the increase in tuberculosis, to be continued until industry regains a proper footing. Another problem which vitally affects the health of the people in both countries is the shortage of clothing. The supply of new material on credit for the manufacture of clothing on the spot would, in the opinion of the signatories, meet the risk of demoralising by the giving of help. Relief for all the hospitals in

<sup>1</sup> See THE LANCET, August 2nd, p. 203.

Austria and Hungary is being administered through a representative medical committee, under the chairmanship of Professor Wenckebach, professor of internal medicine in the University of Vienna, with offices at Singerstrasse 16, Vienna I.

#### MENTAL DEFICIENCY IN PROSTITUTES.

Lieutenant Paul A. Mertz, psychological examiner at Newport News, one of the principal ports of embarkation and debarkation of the American army, records<sup>1</sup> the results of his psychological examination of women arrested for prostitution and similar offences in the course of six months. It is noteworthy that 74 per cent. of the white women and 79 per cent. of the coloured women were found to be infected with a communicable venereal disease. Of 69 women whose ages were obtained, 50 per cent. were under 21 years of age, and over half of these were between 18 and 20. In 126 women in whom the mental age was determined by the Binet-Simon scale, 53 per cent. had a mental age of ten or under, this figure closely agreeing with the 51 per cent. feeble-minded reported by the Massachusetts Commission for the Investigation of the White Slave Traffic in its examination of prostitutes. At the Chicago Morals Court the percentage of mental deficiency among 126 prostitutes was still higher—85·8 per cent. Only 10 per cent. of the cases, however, examined by Mertz were so deficient as to warrant under existing laws segregation in an institute for the feeble-minded. In addition to the mentally deficient, 15 per cent. of the cases showed mental disorder, 11 being emotionally unstable, three epileptic, one a drug addict, and two subjects of dementia præcox. As only few opportunities were given for detecting deviations from the normal, this number is probably considerably understated. The ignorance of the prostitutes, according to Mertz, was appalling, and therefore it is not surprising to learn that 50 per cent. of the women did not reach the fifth grade at school.

#### THE FIRST ANTITUBERCULOSIS DISPENSARY AT NAPLES.

ON June 1st there was inaugurated at Naples, in the Piazza Salerno, near the industrial quarter, the "Preventorium pro Salute," instituted by the Neapolitan Antituberculosis Society. According to *La Riforma Medica* this is the first of the three dispensaries that the society intends to establish in various parts of the city; the second will be built during the present year on a suitable site in the hospital area in the centre of the town, while the third will be erected next year in the western quarter. These represent part of the social programme which has been determined on in order to encourage methods of prophylaxis adapted to the special conditions of the city; later on the other preventive institutions of the society will be added—namely, day sanatoriums, floating sanatoriums, country camps, and open-air schools—leaving to other antituberculosis associations the task of providing permanent sanatoriums and seaside hospitals. It must be acknowledged that the installation of three dispensaries in two years in a city where none previously existed is a record of rapidity and energy which has only been possible when the artificial barriers of small committees have been broken down and in

their place a powerful organisation set up, such as the Neapolitan Antituberculosis Society with its committee composed of such men as Professors Bianchi, de Giaxa, and Jemma, and a band of commercial and industrial men and women well versed in practical philanthropy. The dispensary consists of a central block and two wings, the former having in front a large waiting hall communicating by three openings with a corridor leading respectively to bathroom, surgical and laryngological rooms. The left wing contains an office for the registration of patients, a large laboratory and X ray room, while the right, which faces the south, is occupied by the dispensary, and two ample medical rooms. In the basement are washhouses and stoves for disinfection or destruction. Over the wings are spacious terraces for heliotherapy, while the whole front leads on to a large garden. The medical staff, two of whom are volunteers, are assisted by ladies, who undertake the difficult task of domiciliary visiting for which they are made efficient by a special course of lectures held at the Institute of Hygiene in the University. The choice of a locality for the dispensary, isolated in the middle of a large open space close to the industrial quarter, is happy, and the beneficence of the project and the lavishness of its details have aroused the most enthusiastic approbation of all competent judges. The sound organisation is the outcome of the long study of an expert committee of management presided over by the superintendent, Professor de Giaxa.

#### THE WELFARE OF THE BLIND.

THE welfare of the blind is a matter of pressing importance, even more pressing to-day than heretofore, on account of the large accession which has been made to the ranks of the blind by the ravages of war. Loss of sight is one of the most serious disabilities which can affect humanity, although there are well-known instances of blind persons, such as Milton and Henry Fawcett, who were able to do good work after having lost their sight. When blindness is accompanied by deafness, as too often happens—the latest figures as given in the Report of the Advisory Committee on the Welfare of the Blind, dated June, 1919, show that there were in England and Wales 1009 deaf blind persons, of whom 660 were reckoned as "unemployable"—the disability is enormously increased. We therefore refer again with pleasure to the publication of a circular by the Ministry of Health, dated August 7th, from which we learn that an estimate has been laid before Parliament for a grant to be distributed in aid of certain services carried on for the benefit of the blind. If voted by Parliament this grant will be appropriated in aid of these services from the period July 1st, 1919, to March 31st, 1920, and thereafter, subject to the consent of Parliament, a grant will be payable in respect of each financial year ending March 31st. Grants will be payable to approved agencies (an "agency" is defined as an institution, society, or body engaged in work for the blind) in respect of the following services: workshops for the blind, provision of assistance to home workers, homes and hostels for the blind, home teaching, book production, counties associations, miscellaneous. In regard to the first two services, grants will be allocated at rates not exceeding £5 to £20 per annum per worker or per blind person incapable of work who is cared for in a home. Provision is made for granting to any home teacher employed by

<sup>1</sup> Journal of the American Medical Association, 1919, lxxii., 1597-99.

an agency a sum not exceeding £78 per annum, and grants will be made to any approved agency producing books and music in embossed type. Under the head of "Miscellaneous," we see that the Minister will be prepared to consider applications from an agency for a grant towards expenditure incurred or estimated for any service other than the services mentioned in the regulations, and we earnestly hope that training in music will be considered by the Minister as suitable for a grant, for a blind man who can play a musical instrument with skill is not only a source of great pleasure to himself but may be so also to his fellows. Everyone will remember Thackeray's pathetic account of George III.—old, blind, and mad, solacing himself with Handel. If the suggestions made in the circular are carried out then the lot of the blind will be made appreciably easier than we fear it is at present.

#### MASSAGE AND MASSEURS.

A PETITION to His Majesty in Council has been presented recently to the Board of Trade begging that a charter may be granted to a society to be known henceforward as the Chartered Society of Massage and Medical Gymnastics. The object of the proposed society is to unite the older Incorporated Society of Trained Masseuses, founded in 1894 and incorporated in 1900, with the more recent foundation of the Institute of Massage and Remedial Gymnastics, which was founded in 1916. Such an application has been *in posse* ever since September, 1918, and we can but repeat what we wrote upon the subject in our issue of Sept. 21st, 1918, that it should protect the title of masseur from fraudulent usurpation; and while the council of the new amalgamation should be empowered to coöpt as members all those who can produce satisfactory evidence of training in recognised schools abroad, they must take steps to examine those whose training appears deficient. Only thus can the public be protected from the danger of the un-instructed dabbler in remedial gymnastics, while the elimination of the quack will be in the interest of all genuine masseurs.

#### GENERAL PARALYSIS AMONG JEWS.

GENERAL paralysis of the insane is stated to be a modern disease amongst Jews. Whilst epilepsy has been notoriously rife amongst them from an early date, being mentioned, indeed, by the Talmud writers, general paralysis has practically only occurred in the last 50 years. Sichel<sup>1</sup> finds the reasons for this state of things in the social and religious seclusion in which this people lived from mediæval nearly up to present times, and in their former habit of early marriage. The older Jew was of strict sexual morality. It is quite plausible, therefore, that the Jew suffered less often from syphilis and its sequelæ than did the Gentile. But if a change in life conditions favoured and actually produced more frequent syphilitic infection, then conceivably the type of the disease might be more severe in a race long unfamiliar with it. The same conditions, a pent-up life continuing for many generations, which have resulted in familiarity with tuberculosis, followed by some slight racial immunity to it, have, on the other hand, resulted in unfamiliarity with syphilis and consequent lack of

resistance; in particular lack of resistance on the part of the cerebral tissues. At any rate, the facts of the case will bear some such interpretation. In the first place, the increase of general paralysis coincides in date with the Jew migration from small towns and villages into the great cities, Berlin now containing a quarter of all the Jews in Germany, and New York over a million American Jews. Big cities, of course, offer opportunities for impure sexual commerce, and the life in them is exhausting to the nervous system. In Vienna two different alienists found 20 per cent. of Jews among their general paralytics, and the disease in the whole of Austria occurred more frequently by nearly a third in Jews than in Gentiles. The same phenomenon appeared in London (Beadle), and in Frankfort. However, Russian Jews have (or perhaps one should say had) been compelled to be urban dwellers, agricultural pursuits being forbidden them. Yet general paralysis was rarely observed in their community. The explanation of this is probably that the Eastern Jew is more of the primitive national type than his Western brother, and keeps more strictly to Biblical and Talmudic precepts as to early marriage and pre-marital continence. The Talmud enjoins that every member of the religious community shall be married at 20 years of age. Western social life, especially urban, tends more and more to make such a precept, especially in the upper classes, quite impossible of fulfilment: the age of marriage is commonly much nearer 40 than 20, and pre-marital continence is consequently very much rarer, syphilitic infection very much commoner. It is further confirmatory that general paralysis in Jewish women is as uncommon as in Gentile women: the increase spoken of only occurs in males. Again, it is suspected that alcohol as well as syphilis has a place in the ætiology of general paralysis—it may be an important place, for Mohammedans, who are often syphilitic, but rarely alcoholic, suffer very little from paralysis. Formerly Jewish commercial travellers were those of their nation who suffered most with the disease, but this well-nigh exclusive incidence in one occupation has progressively declined, artisans and the labouring class having become more and more affected. The disease is becoming, as it were, popularised. At all events, the breaking down of national seclusion and tradition has run very closely with the decline in freedom from general paralysis, and the arguments advanced do, as far as they go, suggest a certain measure of causal connexion between the two processes.

#### KÖHLER'S DISEASE OF THE TARSAL SCAPHOID.

THIS condition is described by Dr. F. W. O'Brien,<sup>1</sup> of Boston, who reports a case in a girl, aged 3 years, as probably a non-infectious process, seen only in children and characterised clinically by swelling of the foot, pain on palpation and weight bearing, usually without constitutional signs and with some history of trauma. The disease appears to be due to delayed development of the ossification of the scaphoid, which is stimulated to osteogenesis by traumatism, and the pain and swelling may be due to post-traumatic osteitis. Less than 20 cases have been recorded since Köhler first reported three cases of the disease in 1908. It is probable, as Dr. O'Brien remarks, that both before and since it was frequently mistaken for cold tuberculous abscess. The diseased scaphoid

<sup>1</sup> Max Sichel: *Zeitschrift für Sexualwissenschaft*, June, 1919.

<sup>1</sup> Boston Medical and Surgical Journal, 1919, clxxx., 445-7.

presents the following X ray appearances: (1) It is one-half to one-quarter smaller than usual; (2) its form is entirely regular; (3) its architecture cannot be recognised, the cortex and spongy portion running together; (4) its density is increased two- to four-fold. The prognosis is invariably good, and recovery takes place independently of treatment, though the disease may last two or three years. Rest or support in some form is usually employed.

#### THE STUDENTS' NUMBER.

WE wish to thank all those who helped us so promptly in the production of the Students' Number of THE LANCET, which appeared last week. We desired to revert at the earliest opportunity to our practice for the last 60 years of issuing shortly before the commencement of the October session an educational guide to the medical profession for the use alike of those who are joining it, those who are in it, and their relatives. Circumstances will compel us from time to time to add to the statements made in the last Students' Number, as many things were in course of deliberation and re-arrangement at the time of issue. For example, there were published on Saturday last from the India Office new announcements concerning appointments to the Indian Medical Service. The announcements include the new rates of pay, and those are the same as we were able to publish; while the information in respect of the vacancies and of the circumstances qualifying the applications are now published in another column. We regret as yet to be unable to publish the new rates of pay in the Army Medical Service.

The following corrigendum has been brought to our attention. The Branch Medical Council office for Scotland of the General Medical Council is now situated at 20, Queen-street, Edinburgh, and Mr. T. H. Graham has succeeded Mr. James Robertson as Registrar.

#### THE STING OF THE BEE AND THE WASP.

THE grave symptoms which sometimes follow the sting of a wasp or bee render the observations of Mr. Edward R. Speyer, M.A., F.E.S., Investigator of Diseases of Trees at Oxford University, in a letter in the *Times*, of great interest. Little is known really of the nature of the poison of these insects, but it was for long accepted that the chief toxic agent was formic acid and that, therefore, the prompt application of an alkali to neutralise the acid, such as ammonia or the blue bag, avoided serious consequences. However effective that method may be in the treatment of a bee-sting, it is not only unsound in the case of a wasp-sting, but is likely to aggravate the toxic effects of the subcutaneous injection, for Mr. Speyer now shows that the sting of the bee is decidedly acid, while that of the wasp is distinctly alkaline. If, therefore, the toxic factors are an acid in one case and an alkali in the other, the choice of a neutralising agent is clear, depending upon the particular insect which discharged the venom. But it is doubtful whether the issue is as simple as this, for toxins, apart from any question of alkali or acid, though these may respectively be effective vehicles of toxins, are not negated by simple acid or alkaline applications. The case of the toxin of the serpent fang may be quoted. Still, the evidence is interesting that by extracting the stings of wasps and immersing them for a short time in an acid no

ill-effects resulted when they were driven as deep as possible into the flesh. We have ourselves observed that water in which wasp-stings had been immersed becomes distinctly alkaline, and, further, that the prompt application of vinegar as the nearest acid in domestic service will prevent inflammation. Onion juice, which is acid, acts similarly, and no doubt other acid vegetable or fruit juices would answer equally well. That the bee-sting is acidic and the wasp-sting basic is an interesting differentiation which should be widely known, for not uncommonly the sting proves to be not a simple puncture but the beginning of a toxic process sometimes fatal. A wasp-sting on the moist mucosa, as in the mouth, invariably leads to serious inflammation, with most distressing results. If the simple gargling or washing of the attacked spot with an acid fluid in such a case keeps down the swelling lives may well be saved. The season of wasps is with us, and these observations are therefore opportune. Amongst gardeners there is the belief that the wasp draws its venom from young laurel leaves, which are rightly reputed to contain prussic acid. Wasps certainly are fond of the laurel leaf, but while it seems certain that prussic acid is not the business element of their sting this acid may be the foundation of basic nitrogenous bodies of a toxic nature passed on by the sting. It will be remembered also that wasps, different from bees, are voracious flesh eaters, and meat materials easily enough give rise to basic substances.

THE death is announced of Dr. Alexander Macalister, F.R.S., professor of anatomy in the University of Cambridge, and a member of the Senate of Dublin University.

Two cases of rabies have occurred in the Colchester borough, one on August 15th and one on August 17th, and a third suspected case is now reported. No case of rabies has occurred in the administrative county of Essex.

THE Ministry of Health were notified on August 19th by the deputy medical officer of health of the Port of London Sanitary Authority that a member of the crew of the s.s. *Clan Lamont* was suffering from plague. The vessel was then in dock, but has since been taken into the river and fumigated. The clinical symptoms of the patient are those of plague, but the bacteriologist of the Ministry has been unable to verify the diagnosis, and no plague-infected rats have been found on the vessel. No further cases of illness have occurred on board, and the ship has sailed from the Port of London.

NATIONAL PHYSICAL LABORATORY.—The Lord President of the Council has appointed Professor Joseph Ernest Petavel, D.Sc., F.R.S., M.I.Mech.E., &c., to be Director of the National Physical Laboratory in succession to Sir Richard Glazebrook, C.B., F.R.S., who retires on reaching the age limit on Sept. 18th next. Professor Petavel is professor of engineering and director of the Whitworth Laboratory in the University of Manchester. He is a member of the Advisory Committee for Aeronautics of the Air Ministry. He was educated at University College, London, and undertook scientific research at the Royal Institution and at the Davy Faraday Laboratory until 1898. He was elected John Harling Fellow of the Owens College, Manchester, in 1900, and was scientific manager of the Low Temperature Exhibit of the British Royal Commission for the St. Louis Exhibition, 1904.

## AMERICAN MEDICAL GATHERINGS.

THREE important medical gatherings were held in the United States of America during the month of June. The seventieth annual session of the American Medical Association, which took the form of a "victory meeting" at Atlantic City, from June 9th-13th, has already been reported in THE LANCET.<sup>1</sup> There remain for brief comment the twentieth annual meeting of the American Therapeutical Society, the sessions of which, on June 6th and 7th, preceded the victory meeting at Atlantic City, and the Congress of American Physicians and Surgeons, of which the eleventh triennial session occupied June 16th and 17th at the same city.

At the American Medical Association the afternoon of June 11th was devoted to various aspects of industrial hygiene and their relation to public health, and this discussion, at which Dr. H. E. MOCK (Chicago) presided, merits attention.

Dr. W. J. CLARKE (Worcester, Mass.) dealt with

*Preventive Surgery as Demonstrated by Industrial Practice.*

In the treatment and repair of hernia the question often arose whether the condition was to be classed as an industrial accident. He had found that the sac was often congenital, and there was a distinct racial susceptibility. The question of recurrence was a difficult one. He often saw a sac adherent to the cord, with a small neck, and after amputation of the sac, although the repair appeared to be without a flaw, yet the patient was apt to come back later with a recurrence. No man with a definite bulge should be put to do heavy work.

Dr. W. S. SHERMAN (Pittsburgh, Pa.) said employers were coming to realise the importance of keeping their workers fit, and the immense loss entailed to industry by illness. Fortunately, injuries received in the steel mills were often sterile, as coal, coke, and iron did not produce infection. Dakin's hypochlorite solution, used according to the Carrel technique, had been found a useful solvent of necrotic tissue.

Dr. O. P. GEIER (Cincinnati) indicated how the industrial surgeon might stimulate the patient to seek early advice from an outside surgeon—e.g., in cases of neoplasm or appendicitis.

The PRESIDENT said that the timely examination and removal of diseased tonsils might save such complications as appendicitis and gall-bladder invasion, and even rheumatism. This was an important side of industrial prevention.

Dr. J. W. SCHERESCHEWSKY (U.S. Public Health Service, Washington, D.C.) stated his belief that intra-abdominal pressure was the result of opposition to contraction of abdominal muscles. The development of musculature had much to do with the prevention of hernia and its recurrence. With impaired tonus relapse must take place.

Dr. C. E. FORD (New York) dealt with

*Industrial Medical Practice and Sickness Prevention as a Factor in Public Health.*

Some years ago the employment of a physician was regarded as benevolence on the part of the employer. It was now beginning to be understood that industry would best be benefited by the employment of qualified physicians. Part-time service was of little use. Men adapted to undertake this work were those who had seen at least five years' general practice, had had experience in health department and dispensary work, with opportunity of acquiring the social view-point. Sanitation, nuisances, garbage disposal, sewage disposal, flies, housing, prevention of infection were all subjects of great educational importance. The frank discussion of venereal disease, the control of tuberculosis, the necessity of rest, and the like, were all matters of vital importance. Educational films could now be obtained at a very moderate cost. In a survey of the funds spent by 99 leading industries he found that \$2.50 was being spent per head annually in this way.

Dr. W. A. SAWYER (Philadelphia) said that there were approximately 30 million industrial workers in the United States, and industrial medicine served to reach a class that

could be reached by no other means. There should be coöperation between public health workers and industrial physicians.

Dr. D. L. EDSALL (Boston) stated that at the Massachusetts General Hospital a survey of patients attending the occupational clinic showed that in 5000 cases, or one-tenth of the total attending, occupation had something to do with the disability. The average industrial worker was said to lose eight days in the year from sickness. The opportunity for community service by the industrial physician was illimitable.

Dr. C. HASTINGS (Toronto) gave his experience of the department of industrial hygiene started four years ago in that city. "Show," he said, "the employers of labour how the loss of 10 to 15 per cent. of efficiency in the employee could be saved, and they would be willing to put in good ventilation or any other desired improvement."

Dr. A. WADSWORTH (Albany, New York) spoke of the need for industrial physicians to avail themselves of the facilities offered by the State for laboratory examinations. Systematic examinations in the venereal diseases would be of great industrial service, but if a demand for the work arose there was no doubt that the legislature would see fit to appropriate the proper funds.

Dr. SCHERESCHEWSKY enumerated six lines along which federal management of industrial medicine had been planned:—

(1) Extension of health service in industries to determine extent and means of correcting health hazards; (2) development of system of medical and surgical supervision of employees; (3) securing reports of the prevalence of disease among employees and sanitary conditions in industrial communities; (4) establishment of minimum standards of industrial hygiene and prevention of occupational diseases; (5) improvement of sanitation of industrial communities by coöperating with State and local health authorities and other agencies; (6) medical and sanitary supervision by public health service of industrial establishments owned or operated by Government.

Dr. GEORGE A. SOPER (Sanitary Corps, U.S. Army) dealt with

*The Efficacy of Measures for the Prevention of Disease.*

Of the three great lines of effort—namely, sanitation, public health administration, and personal precautions—only the first two had been developed. Respiratory infections were ten times as numerous as the exanthemata, and personal precautions were the largest factor in this question. Disinfection had come to take a secondary place, and proper ventilation and a high standard of cleanliness had been found of first importance. The soldier had been taught how to take care of himself. The time to study respiratory infections was before the attack appeared. It was for the individual to learn that the lessons of the Army were not for the Army, but to be appropriated by the whole world in times of peace.

Colonel KRAMER (U.S. Army) feared that unless the medical profession approached industrial hygiene in a more scientific and thorough manner they might lose control altogether, as the work was being done most efficiently by sanitary engineers.

Dr. L. I. HARRIS (New York) said it was a pity that after many enthusiastic meetings nothing was done. Resolutions ought to follow the matters discussed and the advice obtained carried out.

Dr. SCHERESCHEWSKY said that the responsibility rested with the community itself. The State and national boards were there for guidance and control. The individual citizen must play his part in demanding the best conditions.

Dr. SOPER, in closing the debate, regretted that only about 70 per cent. of the population were included in the vital statistics of the United States.

The scientific section of the American Therapeutic Society on June 6th opened with an address by Dr. DOUGLAS VANDER HOOFF (Richmond, Va.), the President, on

*Therapeutics and Gastro-Intestinal Disorders.*

In making a diagnosis of gastro-intestinal disorders the services of the internist, the roentgenologist, the oculist, the neurologist, or the surgeon, were, he said, often required. 1000 private cases (excluding definite lesions of the alimentary tract) in which the patients complained of "indigestion" were studied and the causative factors tabulated. Laboratory analyses and X ray pictures were made in all cases, and a Wassermann test was performed. Where

<sup>1</sup> THE LANCET, July 12th, 1919, p. 78.

the presence of more than one lesion was demonstrated the condition most likely to be the causative factor was tabulated. The most frequent cause was found to be chronic appendicitis (one-fifth of all cases); this, with gall-bladder lesions added, made one-third of all causative factors. Peptic ulcer formed one-tenth of all cases. Kidney and heart involvement, one-tenth. Cancer cases formed less than 4 per cent. of the whole. Hypo-acidity was present in about one-sixth of the cases. As regards symptomatology, loss of appetite, though an important symptom in children and in animals, was not prominent in adults on account of the number of artificial stimulants to produce appetite. Coated tongue exhibited no relationship to affections of the stomach. An analysis showed that the same proportion was found in hypo- and hyper-acidity, and that 62 per cent. of perfectly healthy persons had coated tongues. The causes seemed to be: (1) nasal obstruction; (2) absence of friction (as in liquid diet) and where the arch of the palate was very high; (3) perversion of salivary secretion, probably the most common cause and often found in neurotic individuals. Nausea and vomiting were common and found to be due to: (1) toxic states; (2) reflex disturbances from eyes or ears; (3) pharyngeal irritation as in alcoholics and smokers; (4) habit vomiting; (5) brain and spinal cord lesions. These were not frequent in gastro-intestinal disease, except in pylorospasm. Hæmatemesis indicated peptic ulcer or obstruction of the portal circulation. Flatulence was due in most cases to the eructation of atmospheric air that had been swallowed. Abnormal secretion of mucus in the stomach was a protective adaptation against irritating ingesta. Similarly, mucus in the stools was a protective measure of the intestine against the irritation of cathartics. The first treatment for this condition was complete rest for the bowel. Then treatment by belladonna and mineral oil would effect a cure. Indigestion would be found to be caused, not so much by the food eaten as by the state of the gastric nerves during eating. As regards therapeutics, drugs had their place; belladonna was indicated in pylorospasm and digitalis in chronic passive congestion of the liver. In some cases psychotherapy was called for.

#### Discussion.

Dr. T. F. REILLY (New York) said that the last place to look for stomach symptoms was in the stomach itself.

Dr. JACOB DINER (New York) spoke of kidney lesions as the cause of indigestion; these were usually of the chronic interstitial or parenchymatous kind. In the very poorest dispensary class in New York City 65 per cent. of all complaints was of indigestion, and upon investigating the teeth large pus pockets and alveolar abscesses were frequently found. If these people would have their teeth looked after the indigestion disappeared of itself.

Dr. O. T. OSBORNE (New Haven, Conn.) laid emphasis on the character of the food taken. Many persons undoubtedly were eating wrongly. In order to gain weight young people were apt to drink milk as they would water with solid meals, thus putting too much work on the stomach. The giving of digestives, as such, outside of needed hydrochloric acid, was rarely necessary.

Dr. F. M. POTTENGER (Monrovia, Calif.) discussed the question from the standpoint of histology and neurology. Stimulation of the vagus nerve caused increased tension throughout the whole gastro-intestinal tract. Thus, with increase of tension the whole syndrome of appendicitis might be produced, as well as that of hyperchlorhydria. The stimuli did not explode in all individuals at the same time, and appendix stimulation might produce increased acid and motility of the stomach or intestinal tract with irregular contraction and pain in one case, or it might produce intestinal stasis with resulting biliousness in another. A large group of people were vagotonics. The main point in stomach indigestion was to find out whether the case was due to sympathetic or to vagus stimulation.

The regular sessions of the Therapeutic Society were devoted to a discussion on Physiological Researches in their Relations to Therapy, introduced by Dr. J. C. HENMETER (Baltimore) and Dr. R. T. MORRIS (New York); on Glandular Therapy, introduced by Dr. E. B. MCCREADY (Pittsburgh) and Dr. A. A. LESCHNER (Detroit); on Thoracic Affections and their Management, when papers were read by Dr. H. C. GORDONIER (Troy, N.Y.) and Dr. E. ZUEBLIN (Cincinnati); and a symposium on Epidemic Influenza, to which Dr. F. E.

STEWART and Dr. H. C. WOOD, jun. (Philadelphia), Dr. J. DINER, and Dr. N. P. BARNES (Washington) contributed.

#### *The Present Teaching of Therapeutics.*

At the concluding session Dr. S. L. DAWES (New York) gave an address on the Present-day Teaching of Therapeutics. Medicine, he said, had now become a science more or less exact, teaching being based more upon careful statistical data, case-histories, hospital records, laboratory findings than upon exposition of individual opinion. Students were taught to carry out a Wassermann reaction, to do a spinal puncture and examine stomach contents, to differentiate typhoid and paratyphoid, and to have intimate acquaintance with calories, opsonins, and vitamins; but excepting in surgery the cure of disease had become a secondary matter. Materia medica was not taught and therapeutics, with a few notable exceptions, ignored. The pendulum had swung far from the practice of polypharmacy and "shot-gun" prescriptions. The first assault of any magnitude upon this part of the curriculum was made by a clique of medical politicians who arranged the passage of the Medical Practice Act of 1909, when materia medica and therapeutics were removed from the list of subjects in which a candidate was required to pass in order to practise medicine, with the result that osteopaths could practise without any examination of any kind. Not one of the larger medical schools now taught materia medica, and pharmacological teaching consisted for the most part in studying the action of drugs on animals, and did not include the properties and dosage of drugs, their methods of administration, and their incompatibilities. Only two of the first-class medical schools taught applied therapeutics, in most of the 15 it was taught as an accessory. What wonder, therefore, that the practitioner gave fever tablets, kidney pills, coryza tablets, heart tonics, hepatic stimulants, and anti-this and anti-that, while the public crowded the waiting-rooms of osteopaths, chiropractors, Christian scientists and charlatans, or turned to religious newspapers to read the statements of ex-Statesmen and clerical incompetents as to the value of some patent article. The full-time teacher had pushed out the experienced clinician.

An animated discussion followed, in which Dr. VANDER HOF, Dr. DINER, Dr. REILLY, Dr. OSBORNE, Dr. C. E. DE M. SAJOUS, Dr. H. WOOD (Philadelphia), and Dr. POTTENGER took part.

The meetings of the Congress of American Physicians and Surgeons occupied two afternoons, of which the first was devoted to the Surgical, and the second to the Medical, Aspects of Reconstruction.

Dr. SIMON FLEXNER (New York) delivered the presidential address on

#### *Epidemiology and Recent Epidemics,*

basing his remarks on the wave of poliomyelitis which passed over New York and contiguous States in 1916, leaving its mark on a portion of the population during the lifetime of the youngest individuals. Medical literature afforded no parallel for that epidemic. 20,000 cases were recognised, of which one-fourth recovered and one-half are still suffering from the consequences of the disease. In 1917-18 there appeared in the camps of the country, spreading thence to the civil community, an epidemic streptococcus infection, localised in the lungs and affecting the pleura, creating a large amount of sickness and disability among troops, and resulting in many deaths; this infection increased in severity as the disease progressed. But these two visitations were mild and inconspicuous in contrast with the great epidemic of influenza, which caused so many more deaths than the war that the two calamities were hardly to be compared. And yet the havoc of disease left the great mass of people unmoved. It was the duty of the medical profession to ensure that the attitude of the people towards disease calamity was similar to that adopted towards ill-government. In regard to poliomyelitis we had two pieces of essential information—the nature of the germ and its dissemination—but there were things about the microbial origin of this disease which were still hidden. It was not enough for the germs to be identified, there were qualities of virulence, subject to fluctuations and variations, and called forth by circumstances over which we had as yet no control. These phenomena were by no means incapable of being discovered, but results could only go just so far as the public

mind was ready to receive knowledge and to adopt measures which flow therefrom. In regard to the epidemic of influenza, we were confronted with the question whether of that disease we had the essential fundamental knowledge. Epidemics of influenza had been recorded since about the sixteenth century. The great outbreak of 1889-92 coincided with the discovery of the Pfeiffer bacillus, fairly accepted by the world as the cause of influenza. But to-day the position of the Pfeiffer bacillus was not as strong as it was in 1892. The development of laboratories as accessories to medical practice had brought a practical knowledge of epidemic problems and of the application of knowledge to clinical purposes. If it had not been for the disorganisation of forces due to the war there would doubtless have been a frontal and massed attack on the problem. If scientific opinion was still uncertain as to the rôle of the Pfeiffer bacillus, the disease was at all events well under investigation, and certain lines of work, not yet published, were likely to have a profound effect on our views of the microbial origin of the disease. There was a movement towards the belief in a filterable or invisible micro-organism, but the evidence that this type of virus was related to the disease should be just as complete as in the case of a visible organism. The cause, whatever it was, of influenza was mysterious and elusive. It attached itself to persons and was carried about with them. The disease appeared, disappeared, and reappeared. In the history of epidemics influenza took its origin in a region somewhere near the Russian border of Turkestan, spreading along the trade routes as rapidly as transportation moved. In the last epidemic in which the speed of travel had been greatest it spread East and West, to Spain and to China, and in 1919 over the entire globe. Small numbers of individuals were first affected, then larger numbers, then whole communities fell victims. A curve representing the speed of travel of poliomyelitis, compared with that of influenza, showed the progress of the former by weeks and months, of the latter by days and weeks. The curves were extremely similar, first a slow rise, then a steep rise, then a level maintained, then a steep fall or decline. The seeming mystery was, in fact, due to definite causes, like ordinary infections. Particular organisms, the presence of which might or might not cause the actual disease, gained access to the body, the persons carrying it possibly being immune, and yet transmitting it to others. Both these diseases had homes. Poliomyelitis had an endemic home in North-Western Europe. In 1881 it was recorded in Norway and Sweden, where an epidemic outburst preceded the general spread to other parts of the world in 1903-5. If the disease could be arrested in the influenzal stage we should have little to complain of, but we were confronted with the menace of a second disease, pneumonia, more severe, which became grafted on a widespread, relatively innocuous infection. However influenza germs entered the body, we knew that the pneumonia organism entered by the nose and throat and spread under circumstances rendering possible an inflammation of the lungs. Whatever we might think concerning influenza, there was no doubt that we should prevent that most serious complication. What were the proper measures of eradication of these great epidemic calamities? We had a splendid example of eradication of disease in yellow fever. We did not wait for the disease to become epidemic, it was destroyed in its endemic home. The endemic focus of influenza was somewhere on the eastern border of Russia. It was not too much for a reconstructive medical profession to conceive the cleansing up of such a region as that, which by its inaccessibility and its neglect had every 25 or 30 years originated waves of disease spreading over the globe. We might imagine communities intelligent enough to hold their officials responsible for control of disease, as nations have proven that they have held their rulers responsible for control in the war. Communities should be so taxed for public health that they would have the means and power to put into office those best qualified to carry out measures on a parallel with knowledge, holding them responsible, and, if they did their work ill, letting them suffer the consequences.

On the second evening of the Congress Dr. FRANK BILLINGS (Office of the Surgeon-General, Washington, D.C.) gave an address on the Physical and Mental Rehabilitation of Disabled Soldiers of the United States Army, with an exhibition of films illustrating physical reconstruction in the military hospitals.

## MEDICAL MATTERS IN SPAIN.

(FROM OUR OWN CORRESPONDENTS.)

### *Patent Medicines in Spain.*

IN the interests of public health and in response to numerous representations made by the medical and pharmaceutical professions of the country the Spanish Government has at last undertaken to regulate the traffic in proprietary medicines, and to this effect it has promulgated an Order dealing with the manufacture and sale of such preparations equally applicable to national as well as foreign products. It defines a pharmaceutical specialty as "every medicament of known composition, distinguished by the name of its originator or by a fancy appellation, put up in uniform packages and destined for sale in a pharmacy or elsewhere. Preparations the composition of which is partially or totally unknown, as well as those merely stating that they 'are prepared from,' are to be regarded as secret remedies, the sale of which is prohibited." Unless the preparation marketed as a proprietary is made in accordance with a formula contained in the Spanish or in a foreign pharmacopœia, in which case it must be labelled with the official title, and without any additional qualification, it must be registered with the general inspection of the board of health before it may be sold in Spain. Application for registration of a proprietary medicine must be accompanied by the package (in the case of foreign preparations three packages must be submitted), the designs or proofs of the label, wrapper, and prospectuses relating to the preparation, the exact composition, and the grounds which induce the manufacturer to place the product on the market in the form of a proprietary medicine. When registered the preparation may only be sold provided the label and all printed matter referring to it mention the name under which it has been registered, the name of the maker and his profession, where it is manufactured, its composition, the serial number, and date of its registration. Proprietary medicines may only be manufactured by pharmacists or in establishments where the director and the technical personnel are pharmacists. In the case of foreign specialties the professional qualification of the applicant must be certified by the competent health authority of the country of origin on the back of the application for registration.

Questions relating to the therapeutic or pharmacological action of a proprietary medicine submitted for registration will be referred to the Royal National Academy of Medicine for its decision. The health authorities are entrusted with the task of supervising the sale of such products and of enforcing the observance of these regulations. If it is found that the composition of a registered proprietary has been altered, and does not correspond with that entered on the register, its sale will be stopped and a renewed application for registration by the same manufacturer will be refused. The registration in each case is strictly personal, and on the death of the holder, or in the event of his ceding his interest in the preparation to another person, or if the manufacture is entrusted to another party, a fresh application for registration must be made by the new owner. Proprietary medicines which contain potent drugs, defined as all substances of which the maximum initial dose ranges from a fraction of a milligramme to 5 centigrammes, as well as those possessing a drastic, antipyretic, emetic or emmenagogue action, and, in preparations for external use, a caustic or irritant effect, may only be sold in a pharmacy. If the preparation consists solely of one or more drugs answering this description, it may only be supplied on production of a medical practitioner's prescription. The manufacture and public advertisement in any form of any remedies directly or indirectly destined to prevent conception, is forbidden, as well as any references to the possibility of such use. In the case of proprietary medicines at present on sale in Spain, whether national or foreign, a period of two years is allowed in which registration can be effected. All new preparations of this class, as well as the importation of specialties not at present on sale in Spain, must comply with these rules before their sale in Spain is permitted.

### *Marine Sanatorium for Children Suffering from Surgical Tuberculosis at Gorliz, Vizcaya.*

Lately there was opened a magnificent public charity, which, it is hoped, will be a model of its kind for many

others in Spain. The writer first paid a visit to the place some six years ago, when the sanatorium was only in the early stage of construction. Founded by the Provincial Council of Vizcaya and aided by voluntary contributions, its progress to the present state of usefulness has been slow, but the result is highly satisfactory. For situation, plan, and internal arrangements it would be difficult to beat. The model is that of Berck-sur-Mer in France and also, as I was later informed, the Marine Sea Bathing Hospital, Margate. The sanatorium contains 300 beds and is on the Bay of Biscay some 15 miles from Bilbao, lying close to the sandy shore of a little bay, facing due west. It is surrounded by hills, which are only broken in their continuity by a gap which forms the bay. A more perfect arrangement for heliotherapy it would be difficult to plan. As a suntrap the aspect has been specially chosen. The wide verandahs in front and behind each ward are for morning and afternoon use respectively. The flat roof of the central block is also designed for open-air treatment. The sanatorium is a massive stone structure, cemented, and white in colour, with square blue tiles arranged in bands near the top, giving it a curious speckled appearance in Basque style. It consists of three floors with large wards identical in character, the walls and floors tiled, but with the angles duplicated, not rounded, the wider angles affording less lodgment for dust than the gutters of the usual kinds. In all the passages the gutter angle, however, prevails. Each ward contains space for 20 cots, with a cubic space of 50 metres for each. The cot is of white enamelled iron fitted with a movable lattice tray suspended by hooks for the purpose of raising or tilting the hair mattress upon it. A white-enamelled iron and glass locker is beside each cot. So far only 30 little patients are in the hospital, and these, when I last visited the place, were lying in their cots on one of the spacious verandahs outside the wards. They were basking in the afternoon sun on the western side practically in a state of nudity, many so sunburnt as to be peeling, for the doctors believe in the beneficial effects of the direct solar rays on skin tuberculosis and joint disease. Even dressings over open wounds were cast aside and pus welled up by the action of kicking legs. In front of the sanatorium the quiet ripple of the tide was creeping over the sand of a perfect bathing-place, where in suitable cases sea-bathing augments the cure. There is a complete installation for X rays adjoining the operating theatre, sterilising apparatus of up-to-date pattern, shoots for soiled linen, and many ingenious contrivances of a sanitary kind. The water-closets and baths are provided by an English firm, Twyford's. The large laundry in the basement is complete with the latest machinery. The whole building can be heated throughout by steam radiators. The kitchen is in a separate block at the back, and contains the most modern kind of boilers and cookers, worked by super-heated steam. There are buildings for the nursing staff, a chapel, and a special separate block called the "lazareto" for cases of doubtful tuberculosis for observation purposes. The cost of the whole sanatorium when complete will be upwards of £170,000.

## SOUTH AFRICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *A Mild Recrudescence of Influenza.*

THE Union Department of Public Health reports that after the epidemic of October and November last occasional sporadic cases and small localised prevalences have continued to occur throughout South Africa. Up to the end of April last the reported cases averaged 166 and the deaths 10 per cent. of the cases. May ushered in cold weather and increased influenza cases and deaths. It will be seen from the following figures that there was a remarkably large increase in the number of cases—though happily not in deaths—during the last week in June and first week in July. This is the South African mid-winter, and it has been a singularly mild one. The figures have been for the weeks ending—

	Cases.	Deaths.		Cases.	Deaths.
May 17th .....	1025	60	June 14th .....	1701	134
" 24th .....	691	56	" 21st .....	1933	165
" 31st .....	1363	116	" 28th .....	4272	163
June 7th .....	1297	10	July 5th .....	5706	196

Many mild cases escaped notification. While some of the localised prevalences have been fairly severe the disease, generally speaking, has been of much milder type than during last year's epidemic, and with less tendency to pneumonia or other complications. The incidence has been more severe on those localities and classes of population which escaped comparatively lightly last year. Although second attacks are not uncommon, persons who escaped last year are now the principal sufferers. The incidence of the disease on children and elderly persons, formerly light, has now become heavier. At Pietermaritzburg, and in certain other districts, the schools have been closed. The disease has been particularly severe in the Heilbron district, Orange Free State, where there have been over 60 deaths. The severity is now abating, but recent cases have much sooner developed pneumonia than previous ones. It is reported that influenza in the Hekpoort Valley and along the Magaliesberg, Transvaal, is worse than it was last year. Whole households are down in some cases, and, unfortunately, without any doctor, nurse, or medicine being available. Dr. J. Anderson, medical officer of health, Capetown, reported on July 4th that the influenza position in the city is quite satisfactory. Capetown suffered exceptionally severely in last year's epidemic.

### *A Stricken Transport.*

Epidemic influenza occurred on H.M.S. *Kursk*, which left Sydney, Australia, on May 4th, with a ship's complement of 213, military personnel 109, and 995 German internees. There were three doctors and three nurses on board. The vessel arrived at Durban on June 21st, and reported 635 cases of influenza during the voyage; deaths, 1 guard and 16 internees; 94 sick on arrival, 7 very seriously. The vessel was quarantined. All serious cases were landed and isolated in hospital, where two died. The vessel was thoroughly cleansed and disinfected, while the internees were kept on Salisbury Island and the Bluff; no further cases occurred, and the vessel sailed for Europe on June 28th.

### *Tribute to a Lady Doctor at Capetown.*

Dr. Jane Waterston, a medical practitioner and ardent social worker at Capetown, was presented on Friday, July 4th, with an illuminated address, a letter case, and cheque, subscribed for by the citizens, as a small mark of their appreciation of Dr. Waterston's medical, social, and missionary labours during the last 50 years. Dr. Waterston became half a century ago a coadjutor of Dr. Stewart at Lovedale Native College, and, embracing the medical profession, was afterwards a missionary in Nyasaland, following in Livingstone's steps. For the last 30 years she has done a great social work at Capetown, especially for the Free Dispensary there. The Mayoress of Capetown (Mrs. W. J. Thorne) presided at the gathering, and said that the example of self-sacrifice and devotion to ideals of duty displayed by Dr. Waterston in South Africa would be an inspiration to all the women of the country. A letter was read from the Right Hon. John X. Merriman, M.L.A., the G.O.M. of South African Parliamentary life, which concluded:—

"May God bless Dr. Waterston, and may she still live many years to shed the light of her holy and unselfish life over the dark places of South Africa is the heartfelt wish of her admiring friend,

JOHN X. MERRIMAN."

Sir John Buchanan, in paying his tribute to Dr. Waterston, said that she had embraced the medical profession because of her enthusiasm for the succour of humanity, and he had been credibly informed that she had actually walked hundreds of miles on foot in the interior of Africa, all in the cause that she had at heart. Dr. Waterston, in acknowledging the testimonial, said that it was the most trying time of her life. She intimated that she did not propose to leave off public work.

Dr. Alex. Ogg has accepted appointment to the chair of Physics in the University of Capetown.

BELFAST LOCAL GOVERNMENT BOARD MEDICAL INSPECTOR.—Dr. John McCloy has been appointed by the Local Government Board their medical inspector in charge of the Belfast district, in place of Mr. E. F. Stephenson, transferred to another area. This appointment will greatly strengthen the Local Government Board, as Dr. McCloy has a thorough knowledge of modern pathology and bacteriology, and was up to the date of his present appointment senior assistant in the work of the tuberculosis scheme in Belfast.

## NOTES FROM INDIA.

(FROM A REGULAR CORRESPONDENT.)

*Burma Pasteur Institute.*

At the Burma Pasteur Institute during 1918-19 595 persons sought advice as compared with 426 in the previous year. The number of persons bitten by animals of proved taint who submitted to the full course of treatment fell from 183 in the previous year to 105 in the year under review. There were no deaths during the year from hydrophobia amongst those who submitted to treatment, whilst at least four deaths from this cause are reported to have occurred amongst 34 individuals who declined to undergo treatment.

*Influenza Recrudescence.*

The following communique has been issued by the Government of India:—

Outbreaks of influenza are reported from Bombay, Calcutta, Rangoon, and Madras. These outbreaks do not (save in the case of Bombay) appear to have attained serious dimensions. Nevertheless, they coincide in time with the preliminary outbreaks of last year, and though there is at present no reason to apprehend an epidemic of the same proportions the measure of immunity conferred on any individual by a previous attack is uncertain. Accordingly the following steps have, among others, been taken as a preliminary precaution.

The Government of India have suggested to Maritime Governments the taking of power to notify by rule under the Indian Ports Act ship-borne cases of pneumonia, and discretionary power similarly to deal with ship-borne cases of violent influenza. They have requested early intimation of all outbreaks in order that timely warning may be given to the authorities in neighbouring areas and to the public.

Stocks of anti-influenza vaccine are being made ready for early transfer to centres of infection. Surgeons and administrative medical officers are being invited to indent for supplies to be ready on the spot in case of emergency.

A specialist has been deputed to Bombay to deal with the situation.

The Sanitary Commissioner with the Government of India has distributed widely a leaflet dealing with influenza and the course that should be taken in case of an outbreak. This has been communicated to the press. He has specially recommended the use of an aniline nasal douche as an effective prophylactic.

Though there is no immediate cause for alarm, it has been thought advisable to inform the public of these new outbreaks in order that the necessary precautions may be taken and, should the disease show signs of further extension, other communique will from time to time be issued.

Extra medical precautions have been taken at Howrah station to meet returning pilgrims from Puri. It has been ascertained that influenza is raging in epidemic form at Puri. At Howrah doctors treated 40 cases of influenza and 1 case of cholera.

*Infant Welfare Exhibition at Delhi.*

A maternity and infant welfare exhibition will be held in Delhi in February, 1920. It will be reserved for women on certain days, but will be open to men at other times. The proper care of mothers and babies will be shown by means of model exhibits, leaflets, lectures, pictures, magic-lantern slides, &c. The exhibition will be arranged in the following sections: pre-maternity, maternity, infant welfare, childhood, domestic hygiene, and sanitation, first aid and home nursing. A baby show will also be held. The whole will be under the patronage of Lady Chelmsford. It is hoped that this exhibition may be the forerunner of many others both in Delhi and in other cities of India, and that it may lead to a great improvement in the condition of childbirth and the welfare of young children.

*Shortage of Medical Officers.*

A leading Indian journal says:—

We understand that the Government of India are drawing the attention of the Secretary of State to the extremely serious shortage of regular officers of the Indian Medical Service and urging recruitment of a large number of European officers for enrolment permanently. The Government of India have also proposed that certain measures recommended by the Medical Services Committee as likely to increase the attractions of the I.M.S. should be announced in England at once. We further understand that the increased rates of pay for the I.M.S. in civil employment will be announced very shortly, and that these rates will take

effect from Dec. 1st, 1918.<sup>1</sup> This action of Government will help to allay the apprehension created by the grave state of affairs to which we have repeatedly directed attention, and it will also no doubt afford some encouragement to over-worked officers of the I.M.S. who are almost at breaking point. There is no disguising the fact that the present position is well nigh desperate. More than 60 per cent. of the I.M.S. civil officers are still in military employ, and military employments in India are increasing, not diminishing. India itself has been ransacked for doctors to make good the deficiency and the only hope now lies in making the terms of service so attractive that the necessary number of men will be forthcoming from the medical schools at home. We are glad to learn that the Government of India recognise that the matter is one of extreme urgency and are apparently determined to put it right. But it will not be so easy as it would have been before the war to obtain recruits by improving the conditions of the Service. There probably never was a time, indeed, when the opportunities open to medical men at home were so favourable as they are at present. This is an additional reason why there should not be a moment's unnecessary delay in taking the definite action which the gravity of the situation demands.

*War Gratuity of the Indian Army.*

Issuable on the British scale, the Government of India announces that it has been decided to issue to regular officers in the Indian Army, Indian Medical Service, and of the British garrison in India, and to departmental officers with honorary rank of the Indian Unattached List a gratuity for war service on the same conditions generally of those announced for officers of the British Army in Army Orders IV., dated June 7th, 1919. The gratuity will be payable in the case of officers still on the active list on August 4th, 1919, or the termination of war as defined by statutory authority, whichever is earlier. It is not payable to any officer commissioned after February, 1919. Officers who have retired and the legal representatives of officers who have died or been killed in the war should apply for a form of claim to the Secretary, Military Department, India Office, London, S.W. 1.

*New Medical Scholarship.*

Lieutenant-Colonel W. D. Smith, commandant of the Madras Guards, has presented a scholarship valued at Rs.1200 to the Madras Medical College for students in chemistry and drugs.

*Calcutta University Commission*

A summary of the report of the Commission has been published. It concludes as follows:—

We desire to make it clear that certain reforms in the University of Calcutta ought not to be postponed whatever scheme be adopted—namely, the provision of further residential accommodation, the provision of a teachers' training department, the provision of additional accommodation for teaching, and the provision of measures for supervising and improving the health of the students.

August 10th.

## CONTROL OF VENEREAL DISEASES.

*Early Preventive Treatment and the N.C.C.V.D.*

A RECENT deputation from the National Council for Combating Venereal Diseases, led by Sir Malcolm Morris, was received by the Public Health Committee of the London County Council. Its object was to urge the County Council to make provision, through its scheme for the diagnosis and treatment of venereal diseases in London, for early preventive treatment—that is to say, "treatment at an approved centre within a short time after exposure to possible infection." The question also arose of treatment before exposure, and of the alleged objections to such treatment on the side of public morals. It was stated by the deputation that for early treatment to be effectual in the prevention of syphilis, it must be initiated within six hours after exposure to risk. It therefore follows that it would be necessary to institute a very large number of early treatment centres, accessible at all hours of the night and day. The Public Health Committee stated that with one exception the committees of all the London hospitals at which venereal clinics were in operation had definitely expressed the opinion that it would

<sup>1</sup> The new rates of pay for the military and civilian sides of the Indian Medical Service were given in the Students' Number of THE LANCET, August 30th, 1919, p. 393.

be impossible for them to introduce early preventive treatment on these lines. The National Council has made inquiry of medical officers of health of certain provincial towns, but apparently no steps have been taken to provide opportunities for such treatment. The Public Health Committee came to the considered conclusion that quite apart from the moral issues involved, although benefit might accrue in individual cases, yet this would be nullified by the resultant increase in the number of cases exposed to infection. The Committee therefore recommended:—

"That in connexion with its scheme for the diagnosis and treatment of venereal diseases the Council is not satisfied that the public provision of early preventive treatment as suggested by the National Council for Combating Venereal Disease is desirable, and that the National Council be informed accordingly."

We would ask our readers to consider what the result will be if this policy of passivity be persevered in.

1. If we regard the question in its bearings upon public health we shall find that a far larger number of patients would ultimately require treatment for these diseases at a stage when it will be much harder and take more time to effect a cure, whilst in some instances it will be impossible for them to recover. Many sufferers before they recognise themselves as such will have communicated the infection to others. Some of these will be visitors to the large towns, who on returning to their country homes will find it difficult to secure adequate treatment for themselves or their conjugal victims. Whilst we are endeavouring to secure treatment for venereally-infected pregnant women and attempting to treat infants suffering from congenital syphilis and gonorrhœal ophthalmia, we shall be neglecting the obvious course of trying to eliminate the factors responsible for the production of such lamentable results—in other words, we shall be providing wilfully a constantly increasing and preventable stream of maternal and infantile infection.

2. The community will achieve economy if those responsible for its welfare will adopt early preventive treatment. If they do not institute such centres then vastly increased sums will eventually be expended upon institutions at which an increasingly large number of patients suffering from the fully developed disorders will have to be treated. Further, great sums will be called for to maintain the army of parasyphilitic patients in asylums, infirmaries, &c. More medical men will be required for the efficient working of curative clinics as apart from preventive ones; this will entail an augmented salary list and deflection of medical energy from other spheres. The loss to the nation in productive working power through patients incapacitated will be as immense as it will be unnecessary.

Doubtless the National Council for Combating Venereal Diseases will not allow the position to remain as it is, and we ask our readers to augment their efforts.

#### *Hostels for Gonorrhœal Patients.*

Medical officers in charge of venereal clinics are now faced with a variety of problems. A very difficult one is represented by the question as to what to do with patients suffering from gonococcal epididymitis who are unable to carry out the required treatment. Take the case of a man living in a single room, without attendance, unable to obtain a supply of hot water, and so on; he is terribly handicapped, both as regards relief from suffering and ultimate recovery. His treatment entails more work and a greater demand on the resources of the venereal clinics. There is also in these cases a prolongation of the period of infectivity and a greater prospect of sterility ensuing. The general hospitals to which clinics are attached can hardly be expected to give up beds for this purpose; but what objection can be advanced to the institution of hostels to which clinics can send those cases which cannot be treated adequately in their own homes? The dictates of humanity, of national health, and of economy (financial and temporal) demand such a step, which we commend to the Ministry of Health. Once the practical necessity is admitted, the question of sites, staff, and salaries is capable of ready solution.

#### *Travelling Consultants for Venereal Clinics.*

Owing to the rapidity with which venereal clinics are now being formed, it follows of necessity that many of the medical officers in charge of them are practitioners who have as yet had but small opportunity of gaining experience in such work. Cases will be brought before them which

call for an opinion, to be acquired only by a large and long experience. We are assured that medical officers who are possessed by the desire to do the best for their patients and to acquire knowledge for themselves would welcome an expert opinion. Might not the Ministry of Health select a certain number of experts from different parts of the country who would be willing when called upon to visit clinics on the request of the medical officer in charge? Such experts would naturally work under the ægis of the advisor or advisors to the Ministry who have been, or may be, appointed. Since these consultants would only visit a clinic on the invitation of its medical officer, any objection to such a scheme on the score of interference or compulsion would be nullified.

#### *Systematic Care in the Sexual Diseases.*

In an article with this title<sup>1</sup> Dr. James Bayard Clark, U.S.M.C., gives a practical account of the organisation, equipment, and treatment routine at the Genito-Urinary Clinique at Camp Logan. Medical officers in charge of venereal treatment centres and those about to assume such command should study this graphic description with care. Hospitals, municipal boards, and other bodies constructively inclined might gain by assimilating the hints contained therein before beginning to build. The description of the department devoted to early or prophylactic treatment possesses a particular topical interest in view of the present tendency to initiate such "early treatment centres" throughout this country in the interests of civilian health.

## TUBERCULOSIS.

#### *Residential Treatment for Discharged Sailors and Soldiers: Report of the Inter-Departmental Committee.*

THE Committee appointed last April by the Minister of Health and the Minister of Pensions "to consider and report upon the immediate practical steps which should be taken for the provision of residential treatment for discharged soldiers and sailors suffering from tuberculosis and for their reintroduction into employment, especially on the land," has issued its report (Cmd. 317, price 6d.). It is calculated that about 35,000 ex-Service men are suffering from tuberculosis traceable to, or aggravated by, the conditions of service. Of these, about 22,000 have received, or are receiving, residential treatment. Though it is conceded that the priority of treatment hitherto afforded the ex-Service man should continue, it is pointed out that the problem of the tuberculous ex-Service man is only one aspect of a national scourge. The present accommodation for institutional treatment is inadequate, for the number of beds for tuberculosis in the United Kingdom amounts only to 19,500, while only 10,000 to 11,000 of these are available for adult men. The report recommends an immediate and considerable increase of accommodation, as well as the most effective use of existing means of treatment. Generally speaking, Army hutments are unsuited for the treatment of tuberculosis, though the best of them, if used in their present position, may prove, at any rate, of temporary use. It is suggested that local authorities ought to secure these huts, without charge, from the Government.

Of the many schemes submitted to it the Committee find the colony system the best. This would provide (1) sanatorium treatment, (2) training, (3) permanent village settlement with employment under medical supervision, the three sections being intimately correlated in the same area. It is suggested that the Government should at once make provision in the Estimates for £1,000,000 for the finance of village settlements, primarily for ex-Service men. These settlements might be provided by local authorities or voluntary bodies. In the former case the capital sum should be provided by the Government. After, say, five years, the local authorities might contribute to the cost by paying not less than one-fifth of the capital expenditure. The Committee insist on the superiority of sanatorium over home treatment for advanced cases, and urge local authorities and large employers of labour to provide special facilities for employment of those ex-Service men for whom the village settlement is not a satisfactory solution of their difficulties.

<sup>1</sup> Journal of the American Medical Association, April 26th, 1919.

*Paris: Post-Graduate Courses in Tuberculosis.*

Three post-graduate courses in tuberculosis will be given in Paris during the coming academic year under the direction of MM. Bernard, Bezançon, Calmette, Kuss, Letulle, Rist, Sergent, and Teissier. The courses will be of six weeks' duration, commencing on Oct. 20th, 1919, and April 15th and June 15th, 1920. They will be essentially practical in nature, and will include pathology, bacteriology, physical diagnosis, X ray, laryngology, social welfare and dispensary administration. Opportunity will be afforded to the students to work each morning in a dispensary or hospital under the guidance of the lecturing physicians. The course will be open to graduates in medicine who are citizens of France or of allied and neutral countries. The Commission for the Prevention of Tuberculosis in France will grant subventions to a limited number of French physicians. Further details of the course may be obtained from Dr. E. Rist, 5 rue de Magdebourg, Paris.

*Tuberculosis in Norway and Sweden.*

*Norway's expenditure on tuberculosis.*—Since the adoption of the tuberculosis law of 1900 Norway has contributed increasingly large sums to the campaign against this disease. In 1901 the State's budget for tuberculosis was Kr.80,000. By 1908 it had risen to about Kr.250,000; by 1914 to Kr.450,000; by 1916 to Kr.900,000; by 1917 to Kr.1,300,000; and by 1918 to Kr.1,800,000. For the year 1919-1920 the State has budgeted for about Kr.3,225,000. It will thus be seen that since 1901 the funds officially provided for tuberculosis have been multiplied by about 40. This enormous rise is partly connected with the general rise of prices, but the chief factor is the State's recognition of the necessity for constantly undertaking new campaigns against the disease. It realises that the money thus spent is a sound financial investment, directly and indirectly. At present it is estimated that Norway loses every year from tuberculosis the equivalent of about 50 million kroner in working capacity, quite apart from the incalculable distress which the disease brings to thousands of homes.

*The Norwegian National Association against Tuberculosis.*

—The following figures are illuminating as showing what large sums a country, with a population of only a little over two million, can collect by private initiative for the campaign against tuberculosis. The balance-sheet of this association for 1918 shows a total figure of Kr.76,617. The income for the year was Kr.66,520, and of the sums expended Kr.11,786 were devoted to salaries and office expenses, Kr.16,834 to educational propaganda, Kr.12,591 to the education and pay of nurses, and Kr.31,741 to miscellaneous expenses. Included under this heading was expenditure on new houses built to replace old infected houses.

*The Swedish National Association against Tuberculosis.*

This association, which recently celebrated its fifteenth anniversary, owes its inception and organisation in large measure to Sweden's chief administrative medical officer, Dr. B. Buhre. The main feature of the association's programme is a vigorous and organised scheme of prevention. Special attention is devoted to the dispensary system, which provides for the supervision of all tuberculous homes and takes every possible measure to prevent spread of the disease to the healthy from the infected in these homes. The association, which has a membership of 17,000, has trained 165 nurses for this dispensary work, and it has provided three homes for healthy children taken from tuberculous surroundings. In various ways the association has taken steps to prevent the infection of 1200 children in their homes. The income of the association is entirely derived from private, independent sources, and by the sale of its various badges about Kr.1,550,000 have been obtained since 1904. In 1918 alone they brought in Kr.181,000. In 1917, in gifts and legacies alone, Kr.236,630 were received, and interest on capital amounted to Kr.54,980. The total income in 1917 was Kr.508,619.

*Mother of the "May Flower."*—On Feb. 11th last Fru Beda Hallberg celebrated the fiftieth anniversary of her birthday, which was the occasion of many greetings sent her from the various countries that have adopted her idea. Since she started the "May Flower" in 1907 this scheme for collecting funds for the tuberculosis campaign has brought in over 2,000,000 kroner in Sweden alone. It was soon adopted in Norway, where about Kr.900,000 have been contributed. The scheme was introduced in America by Fru Hallberg's sister, who founded the association

"Linnéan" on the 200th anniversary of the Swedish naturalist's birthday. Finland adopted the scheme in 1908, Denmark in 1909. In 1910 Germany adopted it in the form of "Die Blume der Barmherzigkeit," large sums being contributed. Austria and Russia followed in 1911. Since then Holland, Belgium, France, Italy, and England have followed suit.

*Tuberculosis in Germany.*

A week after peace was signed two Americans, Miss Jane Addams and Dr. Hamilton, made a tour of inspection in Germany, and according to the report they have issued tuberculosis has not only become far more prevalent than before the war, but it has also in many cases assumed rapidly progressive and malignant forms, previously regarded as rare curiosities. Professor Kayserling stated that the effect of partial starvation in promoting tuberculosis was so striking that German physicians have begun to regard it primarily as a disease of nutrition, to be controlled much more by appropriate feeding than by the prevention of infection. At present he sees as many cases of tuberculosis in children every month as he used to see in the year. In the course of a visit to Professor Czerny's wards at the Charité, the Americans were informed that fully half of all the children there were tuberculous, and they were shown many hitherto rare cases, such as tuberculosis of the bones of the head, including the upper jaw. At the City Orphanage in Berlin, where v. Pirquet's test used to be positive only in 10 per cent., it had become positive in 30 per cent. But while infection has increased threefold, actual illness has increased fivefold, as shown by the number of cases of skin, gland, bone, and pulmonary tuberculosis. In Halle there is ten times as much skin tuberculosis as there was before the war. All these effects of starvation cannot be ganged simply by estimates of the death-rate; most of the children infected with tuberculosis will not die at once or even show signs of the disease for some time. But, it is estimated, for the next 20 years the tuberculous morbidity will be much higher in Germany than it has been for many decades. One of the agencies through which relief work is being done is "Save the Children Fund," 329, High Holborn, W.C. 1.

## URBAN VITAL STATISTICS.

(Week ended August 30th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 9.7, 10.0, and 10.0 in the three preceding weeks, was again 10.0 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 9.6, and was 0.8 per 1000 below that in the preceding week, while among the remaining towns the rates ranged from 1.9 in Wimbledon, 2.9 in Oxford, 4.0 in Cambridge, and 4.4 in Hornsey and in Lincoln, to 17.1 in Bournemouth, 18.5 in Wakefield, 19.6 in Barnsley, and 22.2 in Exeter. The principal epidemic diseases caused 317 deaths, which corresponded to a rate of 1.0 per 1000, and included 231 from infantile diarrhoea, 32 from measles, 29 from diphtheria, 14 from whooping-cough, 6 from enteric fever, and 5 from scarlet fever. Measles caused a death-rate of 3.5 in Gateshead. There were 1421 cases of scarlet fever and 1004 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1464 and 1063 respectively at the end of the previous week. The causes of 21 deaths in the 96 towns were uncertified, of which 7 were registered in Birmingham and 2 in Rotherham.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 10.0, 9.9, and 10.7 in the three preceding weeks, further rose to 10.9 per 1000. The 246 deaths in Glasgow corresponded to an annual rate of 11.5 per 1000, and included 25 from infantile diarrhoea, 3 from whooping-cough, 2 from diphtheria, and 1 each from measles and scarlet fever. The 73 deaths in Edinburgh were equal to a rate of 11.3 per 1000, and included 2 each from measles and scarlet fever, and 1 each from whooping-cough and infantile diarrhoea.

*Irish Towns.*—The 142 deaths in Dublin corresponded to an annual rate of 18.3 per 1000, and included 37 from infantile diarrhoea, 2 from scarlet fever, and 1 from diphtheria. The 131 deaths in Belfast were equal to a rate of 17.0 per 1000, and included 30 from infantile diarrhoea and 3 from scarlet fever.

**WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.**—At the last meeting of the Committee of this Fund, Sir Alfred Pearce Gould, K.C.V.O., in the chair, applications for assistance were received and grants amounting to £1250 were made to seven applicants. The Committee are prepared to receive applications for assistance from demobilised officers of the R.A.M.C.(T.) and Special Reserve. All communications should be addressed to the honorary secretary, 11, Chandos-street, Cavendish-square, W.1.

# The Services.

## INDIAN MEDICAL SERVICE.

THE Secretary of State for India announces that 204 medical men are urgently required to fill vacancies in the Indian Medical Service. Of these two-thirds (136) will be Europeans and the remainder Indians. The appointment of European candidates will be made by nomination on the recommendation of a Selection Committee in England. Applications from Europeans and from Indian candidates resident in this country will be received at the India Office. Applications from all Indian candidates will be considered together. Appointment will be by nomination on the recommendation of a Selection Committee. Candidates must be over 21 and under 32 years of age at date of application. Preference will be given to candidates who are or have been serving with His Majesty's Forces during the war. All service rendered as a medical or combatant officer, or in a position usually filled by an officer, during the war will count both for promotion and pension on appointment to the Service, but not for the gratuity mentioned below. The scale of pay has recently been greatly increased. A Lieutenant on appointment now receives Rs.550 a month (equivalent at the present rate of exchange, the continuance of which cannot be guaranteed, to £605 per annum). Those who have had three years or more previous service will enter in the rank of Captain on Rs. 700 a month (or £770 a year). An officer who is appointed to the Service in 1919 or 1920 may claim to retire on a gratuity of £1200 on completion of eight years' service from date of permanent appointment, provided he has given notice of his intention to retire 18 months before the date of retirement. An officer so retiring will also be eligible for a free return passage to Europe, if claimed within three months of retirement. Application forms and any further particulars desired can be obtained from the Secretary, Military Department, India Office. The correspondence should be clearly marked on the top left-hand side of the envelope "Medical Recruitment."

The scales of pay accompanying the announcement were published in the Students' Number of THE LANCET last week.

## ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieut.-Cmdr. C. F. Willes is placed on the retired list. Temporary Surgeon Lieutenants transferred to the permanent list of Surgeon Lieutenants:—F. H. Vey, H. L. Pridham.

## ARMY MEDICAL SERVICE.

Major-Gen. (temp. Lieut.-Gen.) Sir C. H. Burtchell, K.C.B., C.M.G., relinquishes his temporary rank on re-posting. Col. S. F. Clark and W. L. Gray, C.M.G., retire on retired pay. Col. E. M. Hassard is placed on the half-pay list under the provisions of Article 351, Royal Warrant for Pay and Promotion.

## ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenant-Colonels relinquish the temporary rank of Colonel on re-posting: H. B. Fawcett, T. C. MacKenzie.

Lieut.-Col. G. B. W. Brazier-Creagh (retired pay) is granted the rank of Colonel on ceasing to be re-employed.

Lieut.-Col. M. Boyle is placed on retired pay. The undermentioned relinquish their temporary commissions on re-posting: Temp. Col. M. G. Foster, (R.A.M.C., T.F.), Temp. Lieut.-Col. Sir T. C. English (Hon. Colonel in the Army, R.A.M.C., T.F.), Acting Lieut.-Col. D. C. L. Fitzwilliams (Captain, R.A.M.C., T.F.), Temp. Major F. A. Hepworth (Captain, R.A.M.C., T.F.).

The undermentioned relinquish the acting rank of Lieutenant-Colonel: Major E. B. Booth, on ceasing to be specially employed; Major F. L. Bradish and Capt. W. W. MacNaught, on ceasing to command a Medical Unit.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Major and Brevet Lieut.-Col. R. B. Ainsworth; Majors G. de la Cour, R. J. C. Thompson, C. R. M. Morris, E. M. Middleton, C. Scalfie, E. C. Phelan, W. J. Weston, W. E. C. Lunn, N. Low, W. J. B. Bell; Temp. Majors T. M. Carter, H. M. Chasseud; Capt. M. White, R. M. Davies.

Major M. P. Leahy retires, receiving a gratuity. To be acting Lieutenant-Colonels: Major M. C. Beatty, whilst commanding a Medical Unit; Temp. Capt. (acting Major) R. Jamison; Temp. Capt. and Brevet Major (acting Major) W. E. P. Phillips, whilst specially employed.

The undermentioned temporary Captains relinquish the acting rank of Major: S. Brown, A. W. G. Woodforde, A. C. Profeit, P. L. Watkinson-Williams, H. E. Rawlence, C. G. Skinner, A. F. Wright, G. Marshall.

Capt. A. L. Krogh and A. S. Crane relinquish the acting rank of Major on re-posting.

**NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.**—The annual conference of this association will be held at the Central Hall, Westminster, on Oct. 16th, 17th, and 18th, the last previous conference having been held at Leeds in 1914. The following distinguished foreigners are taking part in the conference: from France, Professor Léon Bernard, Professor Calmette, Professor Courmont, and Professor Rist; from the United States, Dr. Hermann Biggs, of New York, and Professor William White, of the American Red Cross (Italy); from Italy, Professor Poli, Dr. Rasponi, and Professor Ronzoni. The full programme of the conference is not yet settled, but the main subject of consideration at the conference is the completion of tuberculosis schemes throughout the country in relation to (1) the Ministry of Health; (2) local authorities and Insurance Committees; (3) Pensions Boards and Committees (Discharged Sailors and Soldiers); (4) general

practitioners; (5) Red Cross and other voluntary activities; (6) training of doctors and nurses. The morning session of the first day will be devoted to the consideration of Sections (1) and (2), the afternoon session being devoted to Sections (3) and (4). The subject for consideration at the morning session of the second day, Oct. 17th, is not yet settled, but in the afternoon Sections (5) and (6) will be discussed. The programme of the third day is as yet unsettled. Among those who will address the conference on the first day are Sir R. W. Philip, President of the Royal College of Physicians, Edinburgh, and Dr. Hermann Biggs. Addresses will be given on the second day by Professor Sir William Osler, Regius professor of medicine in the University of Oxford, and by Professor Sir Sims Woodhead, professor of pathology in the University of Cambridge. There will be addresses given during the third day's session on Tuberculosis Work for Red Cross and other Voluntary Workers, but the speakers are not yet arranged. Among the social functions a conversation will be held on the evening of the 16th by the Association, and on the evening of the 17th Lady Glenconner, the wife of the honorary treasurer of the Association, will be at Home.

Dr. John Robinson Harper, O.B.E., of Barnstaple, has received the decoration of Commander of the Military Order of St. Avis, conferred by the Portuguese Republic.

**ROYAL DEVON AND EXETER HOSPITAL.**—The committee of this hospital has accepted a tender for £29,201 for the proposed extension of the hospital, and the work will be proceeded with in sections. Up to the present over £10,000 have been received for the scheme.

**DORSET COUNTY COUNCIL AND TUBERCULOSIS.**—The Hon. Gertrude Pitt has presented Beckford Lodge, Wilts., to the Dorset County Council for the purposes of a sanatorium for tuberculosis patients. The estate is valued at £7000. The county medical officer of health considers the premises suitable for the scheme.

**A GLOUCESTERSHIRE CENTENARIAN.**—Mrs. Arthur Mosley, who completed her 104th year last January, died at Cheltenham on August 15th. She was the widow of the Rev. A. Mosley, and had nine brothers and sisters; the combined ages of the ten show an aggregate of 907 years.

**PRESENTATIONS TO MEDICAL MEN.**—The members of the Redruth (Cornwall) branch of the St. John Ambulance Nursing Association recently presented Dr. Frank Hichens, the divisional surgeon, with a case of surgical instruments in appreciation of his services as honorary lecturer.—Mr. E. J. Domville, consulting surgeon to the Royal Devon and Exeter Hospital, has been presented by the honorary medical staff with a silver bowl and four silver candlesticks in appreciation of his practical patriotism in filling the post of resident house surgeon at the hospital during three and a half years of the war.

**THE LATE MR. W. C. MENCE.**—William Charles Mence, L.R.C.P., M.R.C.S., Temporary Captain, R.A.M.C., died recently at Axminster in his forty-third year. Mr. Mence was medical officer of health for Chard and was honorary surgeon to the Axminster Cottage Hospital. He had been in practice for some years in Axminster, where he was widely known and respected. He joined the R.A.M.C. shortly after the commencement of the war, and had served in Egypt, Mesopotamia, and France. He had only recently returned from active service. Much sympathy is felt locally for his widow and children.

**DIPLOMA IN PUBLIC HEALTH.**—A course of lectures and demonstrations, extending over three months, will be given at the Western Hospital, Seagrave-road, Fulham, S.W., by Dr. R. M. Bruce, medical superintendent, on Tuesdays and Fridays, at 5 p.m., beginning Tuesday, Sept. 30th. The fee for the course is £3 3s. Medical men desiring to attend the course are required, before attending at the hospital, to pay the above-mentioned fee to the Clerk to the Metropolitan Asylums Board (Sir T. Duncombe Mann), Embankment, E.C. 4, giving their full name and address.

**SOCIETY FOR THE STUDY OF INEBRIETY.**—An autumn session will be held in the rooms of the Medical Society of London on Oct. 14th, preceded by a breakfast at 8.30 A.M. at the Polytechnic. The sessions commence at 10.30 A.M. and 2 p.m., followed at 5.30 p.m. by the eighth Norman Kerr lecture at the house of the Royal Society of Medicine on the Relation of Alcohol and Alcoholism to Maternity and Child Welfare, by Mrs. Mary Scharlieb, C.B.E., M.D. Communications should be made to the honorary secretary, Dr. T. N. Kelyack, 139, Harley-street, London, W. 1.

## Correspondence.

"Andi alteram partem."

## THE CONDUCT OF LABOUR AND PUERPERAL SEPSIS.

To the Editor of THE LANCET.

SIR,—There are just three points in Dr. R. L. Kitching's letter in your issue of August 23rd to which I will briefly reply.

1. The cause of conjunctival inflammation during the first week of life of the newly-born child. For this Dr. Kitching suggests a chemical irritant in the vagina, possibly lactic acid. We know that in strengths of 50 to 75 per cent. solutions lactic acid is a caustic. We shall therefore not be far wrong if we assume a 10 per cent. solution of the acid in the vaginal discharge during labour to be necessary for the production of actual inflammation of the conjunctiva. It is characteristic of all chemical irritants that they produce their effects within a very short time of application. It therefore follows that ophthalmia should declare itself in the eyes of the child at latest within two or three hours of birth. The delay of from four to seven days before it makes its appearance seems strange on this hypothesis. There is also another difficulty in the way, and that is the presence of lactic acid itself in the vaginal discharge in concentration sufficient to produce the required result. The information which Dr. Kitching would like to have as to what numbers become infected after birth was arrived at many years ago, and was apparent, not only to those who attended labour in those days, but also to ophthalmic surgeons who saw the end-results of ophthalmia neonatorum in these eyes. It would be impossible to obtain statistics now because we eradicate and suppress the evidence of maternal infection by immediate attention to the eyes of the newly-born child. There is also one other fact that points to the maternal passage as the source of infection—and that is, that after the first week of life the susceptibility of the child to acute inflammatory infections of the conjunctiva vanishes, although its environment remains the same.

2. While admitting the soiling of the genital passages in the various ways that I pointed out, Dr. Kitching believes that the vagina is able to deal with these organisms and sterilise itself. The vagina, so far as one can see from its structure, possesses no means of defence against intruding organisms. It has no adenoid tissue, no glands, and it is lined with squamous epithelium. It has, however, a great many folds and recesses, within which organisms would find a convenient resting place. Nor has the uterus any particular power, so far as we know, of destroying organisms. The spread of venereal disease shows the vagina is powerless to deal with invading organisms, and the occurrence of gonorrhœal ophthalmia in the newly-born child is proof positive that the vagina of the pregnant woman is equally defenceless. The argument from analogy furnishes just as conclusive proof that cavities and canals far more highly endowed by Nature than the vagina to deal with organisms are often powerless to rid themselves of their invaders. I need only point out the persistence of Klebs-Löffler bacilli, meningococci, and pneumococci in the naso-pharynx for months; of *Bacillus typhosus*, *B. paratyphosus*, bacillus of Shiga, and streptococci in the bowel; of *Bacillus coli* and streptococci in the urinary passages.

3. The operation area in a confinement extends from uterus to perineum, and the management of a normal labour is primarily the care of a wound. In an ordinary operation the surgeon inflicts the wound and is careful to interfere with it as little as possible. In labour Nature inflicts the wounds, and in doing so pours out a serous exudate with intent to sterilise and wash out the passage along which the fetus will pass. I tried to point out the various ways in which sepsis might be introduced into the maternal passage before labour began, and instanced conjunctival infection of the newly-born child in proof of my contention of vaginal sepsis. Until ophthalmia neonatorum has been explained away and the maternal passage exonerated it is a legitimate assumption that the operation area of the medical attendant at a confinement may contain septic organisms before labour begins, and that great caution should be exercised in the making of internal examinations. To Dr. Kitching this is only worth a ponderous joke.

I am, Sir, yours faithfully,

Steele's road, N.W., August 24th. 1919.

J. H. E. BROCK.

## THE VERNON-HARCOURT INHALER.

To the Editor of THE LANCET.

SIR,—In your obituary notice of the late Mr. A. Vernon-Harcourt, F.R.S., you animadvert upon the chloroform inhaler associated with his name. I am sure the writer has no wish to prejudice the use of the inhaler by a rather disparaging criticism upon it. It is suggested that "clinical authorities" maintain: (1) "that chloroform accidents cannot be entirely prevented by regulating chloroform percentages"; (2) the inhaler proves useful for cases "in which a light anaesthesia" is required; (3) the risk of using a dosimetric inhaler is that while it suggests security it may divert the anaesthetist's attention from his patient's condition. Some confusion is caused by mixing the findings of the Chloroform Committee with the use of the inhaler. The Committee never stated that any inhaler or method could wholly avert chloroform fatalities. It, however, contended that such deaths were commonly the result of employing concentrations of vapours the strength of which could only be guessed at by the anaesthetist. This applies alike to excessive or too tenuous strengths of vapour. The Committee, not Mr. Harcourt, adopted the 2 per cent. value as the usual maximum, following the findings of Paul Bert and others. This was done after a great deal of careful experimentation, the protocols of which are to be found in the report. Mr. Harcourt's inhaler can be graded for any strength vapour, it is a question of physics, but he was requested to adopt the 2 per cent. maximum. This was done, although during experiments 2.5 per cent. and 3 per cent. vapours were used from the inhaler. A simple device secured this.

Of course I do not know what clinical authorities are referred to, but I doubt whether those who criticised in the way indicated had enjoyed a wide experience of the use of the inhaler, say a thousand or so cases. As to the third point, having had a rather wide experience in the use of the Vernon-Harcourt inhaler, I may, perhaps, be allowed to quote from my article dealing with the matter,<sup>1</sup> which received the approval of the Committee. I wrote:—

"It cannot be too strongly insisted upon that the Vernon Harcourt regulator is only a means to an end. It supplies a fairly accurate method of regulating the percentage of chloroform presented to the patient, but it does not, nor can any inhaler, abrogate the necessity for a competent knowledge of the action of chloroform on the human subject and experience in administering that anaesthetic. The apparatus need not, and must not, detach the chloroformist's attention from his patient's condition; it merely enables him to increase or decrease the dose of chloroform as may be necessary. Observation of the patient's condition will indicate when the necessity arises."

Finally, I should like to suggest that the implication that the Vernon-Harcourt inhaler is only useful when a light anaesthesia—i.e., a narcosis below Snow's third degree—is required is inaccurate. It can induce full anaesthesia and even a deeper narcosis in cases of prolonged administration. This assuming that the person using it does so efficiently.

I am, Sir, yours faithfully,

August 29th, 1919.

DUDLEY W. BUXTON.

\* \* We had Dr. Buxton's book before us, and noted the passage which he quotes. Other authorities disagree with Dr. Buxton as to the range of utility of the ingenious Vernon-Harcourt inhaler.—ED. L.

## THE INCIDENCE OF TUBERCULOSIS AMONGST ASYLUM PATIENTS.

To the Editor of THE LANCET.

SIR,—The paper on this subject by Dr. F. A. Elkins and Dr. Hyslop Thomson in your issue of August 9th and the subsequent letters from Dr. F. E. Tylecote and Dr. H. K. Abbott have been read by me with great interest, for I was chairman of the Tuberculosis Committee of the Medico-Psychological Association appointed in 1901, and have taken always a keen and active interest in tuberculosis, not only among the insane, but also among the poorer classes in this country. The Tuberculosis Committee of the Medico-Psychological Association was elected as a result of an excellent essay by Dr. F. G. Crookshank, which gained for him the medal of the association, and which was published in the *Journal of Mental Science* in October, 1899. Dr. Crookshank's clear and concise conclusions were endorsed in the Report of the Tuberculosis Committee, who received from medical superintendents of the asylums for the insane in Great Britain invaluable answers to specific questions.

<sup>1</sup> *Anæsthetics*, p. 249.

This Report was, unfortunately, shelved by reason of minor errors in the statistical figures, though it was admitted by the Association that these errors in no way altered the real value of the document. The Report was published, and can no doubt be obtained from the secretary of the Medico-Psychological Association.

Practically very little has been done, and the death-rate of tuberculosis in asylums is still increasing. The Board of Control recognise this fact, but simply make recommendations and insist on nothing. If they have no power under the Lunacy Act of 1890 to enforce their recommendations, why do not they obtain that power or urge the Ministry of Health to obtain it for them? I have pointed all this out in a recent book of mine. Something more must be done. A Ministry of Health is about to open a campaign for the physical improvement of the nation. To my mind the whole question of the death-rate of tuberculosis in our large asylums is a standing disgrace to our country, and I earnestly hope something will soon be done to mitigate this crying evil.

I am, Sir, yours faithfully,

Bournemouth, Sept. 1st, 1919. L. A. WEATHERLY, M.D.

### INJECTIONS OF TARTAR EMETIC IN BILHARZIASIS.

To the Editor of THE LANCET.

SIR,—In a paper on this subject published in your issue of August 9th Dr. Frank E. Taylor draws attention to the risk of antimony poisoning as the results of intravenous injections. He goes on to say that the toxicity of arsenic has been greatly reduced by introducing it in organic combination, and that it would appear highly probable that similar organic compounds of antimony could be produced combining equal therapeutic effects with diminished toxicity. As no further allusion to any such substance was made either by Dr. Taylor or by Dr. J. B. Christopherson in his letter on the same subject in the following issue, it may interest your readers to know that Dr. G. Caronia, editor of *La Pediatria*, has experimented as far back as 1916 with preparations of antimony as injections in external kala-azar and leishmaniasis. He gave the preference to acetyl-p-aminophenyl, stibiater of sodium, on account of its greater efficacy, easy absorption, and less toxicity. It is freely soluble in distilled water and contains 38.5 per cent. of antimony, and may be given in doses up to 20 cg.

I am, Sir, yours faithfully,

T. VINCENT DICKINSON.

Cadogan Mansions, S.W., Sept. 2nd, 1919.

### EARLY MENTAL HOMES.

To the Editor of THE LANCET.

SIR,—It was recently stated, in answer to a question in the House of Commons, that the provision of convalescent homes for early uncertifiable mental cases (without detention and on a purely hospital basis) would come under the province of the new health authority. It is admitted that such homes would be a great boon in intercepting cases (especially those occurring among ex-soldiers) who would otherwise be relegated to asylums. The Lunacy Board, according to its annual reports, has long desired the institution of "reception houses" under its wing where early cases could be detained, say for six months, without certification—i.e., without any judicial investigation or appeal. A Bill with this object, entitled the "Mental Treatment Bill" was introduced by the Home Office in 1915, but had to be withdrawn, the House of Commons regarding it as an annulling of the safeguards of the Lunacy Act and an infringement of the rights of the individual. From recent indications it appears that a similar Bill is now again in contemplation. The Lunacy Board has, however, no jurisdiction over uncertified and uncertifiable persons; and in order that cases in the very early and most curable stages should be induced to enter these homes voluntarily (as they would enter a hospital), it is essential that the homes should have no connexion with lunacy, else they will be regarded as "half-way-houses" to asylums, and shunned by the very people for whom they are intended. Public money, if sunk in such homes, will be for the most part entirely wasted.

It is a mistake to think that legislation is needed for the provision of sanatoria which do not involve detention. The Public Health Act, 1875, has already conferred on borough

councils the power to run hospitals, and similar powers could be readily extended to the London County Council and county councils generally. The cheering and hopeful atmosphere produced by the fact that the terms, both of admission and of stay, are *voluntary*, is in itself a most important factor in recovery. It is not the existence of legal safeguards which creates "stigma," but the fact of being subjected to detention. It is in the interest of the public that every case in which restraint is applied should be carefully investigated under judicial procedure, and the salutary provision contained in Section 315 of the Lunacy Act ought to be strengthened and not annulled. On the other hand, every case proved to be "dangerous and unfit to be at large," ought to be certified, and no trivial and uncertifiable case ought to be subjected by any underhand method to detention.

I am, Sir, yours faithfully,

S. E. WHITE, M.B., B.Sc.

Upper Montagu-street, W., August 21st, 1919.

### THE ETIOLOGY OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—Captain G. E. Beaumont in his paper on this subject in THE LANCET of August 9th records that examination of material from influenza patients has shown the presence of a "mycotic organism." I do not wish to comment on his results beyond saying that there must be rigid proof before one can accept "hyphae, large spores, coccal clusters, small spores, tetrads, mulberry masses, chains of cocci, bacilli" as pleomorphs of the same organism. My object in writing is to point out how inadequate from the point of view of a systematist are the figures of fungi usually appearing in medical literature. In the present instance it is impossible from the diagram to hazard a guess as to the fungal genus in which the hyphal stage of the organism would normally be placed. The manner in which the spores are borne is the important point in classification, and this should be clearly shown in any figures. This can rarely be made out in film preparations, but is best studied by mounting the fungus in absolute alcohol; the preparation may be made more permanent by running in dilute glycerine and "ringing" after a week or so.

I am, Sir, yours faithfully,

J. RAMSBOTTOM.

British Museum (Natural History), August 26th, 1919.

### THE RESULTS OF COMPLETE COLECTOMY.

To the Editor of THE LANCET.

SIR,—In your issue of August 9th there is a letter from Mr. J. F. Dobson, of Leeds, in reference to a paper of mine on colectomy, in which he says that the operation of complete colectomy will remain under a cloud as long as those surgeons who perform it are content to support their views by the publication of their cases in an imperfect manner. Mr. Dobson's criticism is, up to a certain point, merited, in that very few details of the after-histories of my cases were appended, but the implication that discredit must, as a consequence, fall upon the operation because such histories were unknown or unfavourable, cannot pass without comment. At the time of writing I was perfectly well aware that the condition of the patients to whom I referred was satisfactory, but I had not sufficient recent detail to make it worth while to do more than indicate in a general way that the results of the operation were good. Perhaps I took for granted in my realisation of this fact that critics would accept it as a matter of course. Since Mr. Dobson's letter appeared I have communicated with my patients again, and I hope that he will agree that the details supplied now bear out the general statement made in the paper.

Mr. Dobson mentions specially the after-progress of Cases 1 and 2. In a letter I have just received from Case 1 are these remarks: "I am in good general health; I get no pain after eating, as before the operation. I believe the operation to be a great success." He goes on to say that he is employed in one of the shipping lines in Liverpool. Nearly two years have elapsed since I operated on him. Case 2 writes that he was playing football ten weeks after the operation, and that he has had no trouble with his bowels, although they move three times a day. This colectomy was done six months ago. Mr. Dobson finally deprecates the absence of "a full description of the diseased condition of

the rectum held responsible for the imperfect recovery of Case 3." But surely if a patient has ulcerative colitis of such severity as to endanger his life—as stated in my paper—and, if, after removal of the colon, he still for a time continues to pass mucus and blood in his stools, it is fair to conclude (without submitting the patient to another anæsthetic for sigmoidoscopy) that the persistence of some of the symptoms is explained by the presence of ulcers in the only remaining portion of the large bowel. This inference is supported by the statement made in the description of the case that the symptoms improved under rectal lavage and vaccine treatment. This patient has just written that he has improved very much since leaving hospital six months ago.

It is only fair to add that since my paper was written I have been asked to see Case 4 again, and have found that after 18 months of perfect health she had been taken ill with headache and vomiting. I discovered a nodular enlargement of her liver, and evidence of a metastatic growth at the base of her skull. Still, I think it is surprising that she remained well so long after the removal of such an advanced cancer of the bowel, and I do not think that anyone could regard her present condition as in any way attributable to the removal of her colon.

I am fully cognisant of the severity of the operation, and agree that it should be undertaken only to relieve a very serious condition. But I feel quite certain that there are many people whose suffering can be relieved in no other way, and I wrote the paper with the object of showing that it was possible for the operation to be performed with a moderate degree of safety even by such a tyro as myself.

I am, Sir, yours faithfully,

JAMES TAYLOR,

Aldershot, August 26th, 1919.

Major, R.A.M.C.

## THE ORIGIN OF LIFE: THE WORK OF THE LATE CHARLTON BASTIAN.

To the Editor of THE LANCET.

SIR,—In your issue of August 16th Commander W. Bastian, R.N., now objects to the tubes used in my experiments. I have stated that "the tubes employed were the same as those used by Dr. Bastian,"<sup>1</sup> but as this seems insufficient I have written to the makers, hence the delay. They reply: "The tubes were made no doubt from soft German glass tubing, in every way the same as those supplied to Dr. Bastian." (August 20th, 1919.) Evidently Commander Bastian was misled by the word "hard," which was only used relatively, not as equivalent to Jena glass.

Commander Bastian seems still doubtful whether the experiments are not invalidated because some of the tubes were kept three years. I have explained that samples were opened about every three months, but that Professor Hopkins considered it unnecessary to give details about the whole 100 tubes. As a matter of fact, I fail to see why all the organisms must be dead in three years. Because if the conditions were ever such as to produce life, there is no reason for the conditions to change; and "organisms" would be continually coming into being and dying. Since the mass of the "organisms" is infinitely small compared with that of the salts, "live organisms" should be found after any length of time, however short-lived they might be, because the process of formation would continue until the salts were exhausted, or until some harmful end-product had been elaborated. Dr. Bastian himself uses this form of argument to prove that abiogenesis is still taking place. "Relying on the uniformity of natural phenomena, we have a right to believe ..... that the processes which originally led to the growth of living matter would constantly tend to be reproduced."<sup>2</sup> I should like to add, the object of my experiments was to test whether I could repeat Dr. Bastian's results. Therefore all possible precautions were taken to reproduce his conditions, by the use of the same samples, the same tubes, and the same laborious method of sterilisation. I am fully aware of the difficulty of proving a negative, therefore, though others as well as myself have had negative results, I agree with Commander Bastian in hoping he may have the satisfaction of seeing the work repeated. The positive results of one man can only be disproved by the

general consensus of opinion derived from a number of negative results—as in the case of the well-known N-rays, which have been relegated to the category of fancy observation.

I am, Sir, yours faithfully,

The Biochemical Laboratory, Cambridge,  
August 22nd, 1919.

H. ONSLOW.

## LIFE INSURANCE AND WAR DISABILITIES.

To the Editor of THE LANCET.

SIR,—There are many questions in life insurance connected with injuries and ailments incurred during active service on which data are required. As far as mechanical injuries go there is probably nothing very novel. Limbs have been lost and injuries by bullets sustained by so many in previous centuries that a fairly clear actuarial estimate can be made of their bearing on longevity. More pressing questions are, among others, these:—

1. *Gassing*.—So far as I have seen at present a man who has been badly gassed exhibits objective signs in his lungs. Is he going to be more liable to bronchitis, pneumonia, &c.?

2. *Trench nephritis*.—Is this permanent in a majority or minority of cases? and what is the ultimate condition when the albuminuria does not clear up?

3. *Shell shock*.—Admitting the vagueness of the term, one would wish to know how far the nervous stability of the individual is likely to be affected and whether there is any connexion between the severity of the original condition and the probable sequelæ.

4. *V.D.H. and D.A.H.*—Of all the unfortunate legacies left us by the war I fear that few will lead, or have led, to more pitiable distress in the uneducated or even the educated soldier. Thousands of men are leading valetudinarian lives and causing untold anxiety to their dependants and friends because at some time their hearts responded naturally to an unaccustomed call upon their reserves. Once a man has been told, "There is something wrong with your heart," it makes him in nine cases out of ten a derelict member of society. In ninety-nine cases out of a hundred there is nothing wrong, and in the other case usually nothing that matters. An examination of all these cases by competent cardiologists would probably save tens of thousands of pounds and give back to thousands peace of mind and desire to work. It might do the latter and it might not. Personally, I have seen few cases in which the individual labelled with one of the two tags could not lead a normal life, and none that believed me. What is the best empirical test for gauging cardiac muscle condition?

Other ailments will suggest themselves, but those I have mentioned are perhaps the commonest. On the three first any data would be most welcome to those engaged in trying to foretell the future of the individual.

I am, Sir, yours faithfully,

Birchin-lane, E.C., August 26th, 1919.

C. WYNN WIRGMAN.

## CRYPTOPODIA.

To the Editor of THE LANCET.

SIR,—The condition described by Dr. E. C. Bousfield under the name "cryptopodia" in THE LANCET of August 23rd is of some interest, but I doubt if it should be described as a new disease, or even as a disease. An œdematous swelling of the feet, and sometimes of the legs, is not very unusual in the infective type of rheumatoid arthritis; in patients who sit for long hours with their legs in a dependent position this œdema may become marked and resemble that seen in elephantiasis. This swelling usually subsides gradually if the limbs are kept in a horizontal position, and more quickly if massage is ordered.

Dr. Bousfield's patient seems to show this œdema in an exceptionally severe form; it is, of course, possible that in his case the condition is due to some other cause, but as he states the patient suffers from rheumatoid arthritis and does not discuss the above type of œdema in his differential diagnosis, may I point out the possibility of this being a simple explanation of the change.

I am, Sir, yours faithfully,

T. S. P. STRANGEWAYS.

Research Hospital, Cambridge, August 27th, 1919.

To the Editor of THE LANCET.

SIR,—When Dr. E. C. Bousfield demonstrated the above-named remarkable case at the recent meeting in London (July, 1919) of the Association of Physicians of Great Britain and Ireland, I had the good fortune to be present,

<sup>1</sup> Proc. Roy. Soc., vol. xc., p. 286.

<sup>2</sup> "Origin of Life" p. 7.

though his illustrated description in THE LANCET of August 23rd gives one an almost equally exact idea of the condition. I venture to suggest that it represents an *extreme* form of the class of cases which I have referred to under the heading, "Baggy Subcutaneous Fat Simulating Symmetrical Oedema of the Legs; Disorder of Internal Secretions." An outline drawing by Mr. Shiells illustrates the account of the case, which I showed at the Clinical Section of the Royal Society of Medicine on March 14th, 1913 (Proceedings, 1912-1913, vol. vi., p. 167). I should have spoken of "baggy subcutaneous tissue" rather than of "baggy subcutaneous fat." In my description I said: "There is chronic swelling of the subcutaneous tissue of the legs below the knees of one or two years' duration. This is symmetrical, and in both legs tends to *bag above the ankles*. It either does not pit at all, or it (sometimes) pits slightly on pressure." The patient in question was a woman, aged 40 years, in whom menstruation had ceased six years previously. The thyroid gland could not be distinctly seen or felt. Unfortunately an only very imperfect trial of thyroid treatment was made. There can be no doubt that in similar cases obvious symptoms of thyroidal disorder are sometimes present.

I am, Sir, yours faithfully,  
F. PARKES WEBER, M.D., F.R.C.P.

London, W., August 23rd, 1919.

### THE TREATMENT OF "BORDER-LINE" PENSIONERS.

To the Editor of THE LANCET.

SIR,—The question and answer reported in your Parliamentary page<sup>1</sup> regarding the treatment and accommodation of neurasthenic and "shell shock" pensioners on the borderline of lunacy call attention to a defect in the present administration which many of us engaged in this work have constantly brought before us. A serving soldier in a neurological hospital can, if necessity arises, be transferred quietly and without publicity to an asylum, where he is not certified until ample time has elapsed to make it evident that there is no alternative. What happens to the unfortunate discharged soldier who is similarly situated? Before he can be admitted to an asylum he must be certified and be removed by the Poor-law authorities—i.e., as a pauper. It is true that once admitted he is transferred to the "Service patient" side, but why should he not be treated similarly to the serving soldier, thus avoiding the stigma of certification and pauperism.

Medical officers of neurological hospitals are often reluctantly compelled to refuse cases such as these, which might benefit considerably by treatment, owing to the unavoidable delay, publicity, and detrimental effect on the other patients which ensue if it should become necessary to send them to an asylum through the present Poor-law channels. Moreover, a man may require closer control than the average neurological hospital can provide without being certifiable.

I am, Sir, yours faithfully,  
X.

August 23rd, 1919.

### THE POSITION AND PAYMENT OF THE PENSIONS BOARDS.

To the Editor of THE LANCET.

SIR,—I have noticed several letters in THE LANCET complaining about the insufficiency of the rate of pay given to the members of Pension Boards. I agree that the pay is quite insufficient to attract capable men, but there is a worse grievance than the pay, and that is the conditions of work. I am speaking of the boards at Westminster, in Clock Tower Gardens. Until a few days ago we had a

long form, either 179 A or A <sup>36</sup>/<sub>C</sub> to fill in *in duplicate*, when the second copy could well have been made by a clerk; and the chairman had to sign his name an average of eight times in each case examined, the members not quite so often. This was bad enough, but within the last few days the card index system has been introduced, and two cards and one long form are now used in each case. These cards contain a résumé of the pensioner's medical history, and précis of all previous medical boards. No doubt they will be very useful, but they should be filled up in a quiet room by a capable medical man some time *after* the

board. While the chairman is making out this card one of the members is either making out a duplicate, or is filling up the long form, thus leaving the third member free to do the examination of the pensioner. He is hampered greatly in this work because the chairman, in order to fill up his card correctly, must keep the documents—M.H.S., &c.—under his eye, so that the examining doctor has nothing to guide him in the search for a disability. Later on, the card having been filled, the documents are released, and may be consulted, but much valuable time has been lost, and the examination is necessarily not so complete as if engaged in by two or by all of the members of the board.

Before this card system was introduced each board examined about 9 cases; now under the card system only 5 or 6 can be examined during a session, and even then not examined so carefully as before. The expense is great and the waste of public money is to be deplored when one considers that there are three members of each board, with supervising officers and clerks, orderlies, &c., to be paid for.

I am, Sir, yours faithfully,  
August 20th, 1919. MEMBER OF PENSION BOARD.

To the Editor of THE LANCET.

SIR,—I read "Medico's" letter in your issue of August 16th on the status of members of pensions boards with great interest. Our fees are certainly inadequate, but he has omitted to state that these are always several weeks in arrears. We were kept waiting till July 23rd for our June fees. Thus we were seven weeks without any pay. We have not yet received any pay for the month of July, although it is, when I write, approaching the close of the month. We feel strongly on this point. Payment should be made when it is due.

I am, Sir, yours faithfully,  
August 20th, 1919. DEMOBILISED MEDICO.

### THE MARRIAGE OF ASSISTANT MEDICAL OFFICERS AT ASYLUMS.

To the Editor of THE LANCET.

SIR,—I hope that the letter of "Dismissed" in your issue of August 9th will not pass without proper notice. Such injustice cannot be too strongly condemned. At a time when we have just concluded a war for freedom and justice to think of this instance of man's inhumanity to man and to his rights as a citizen makes one rise in anger and protest. What possible harm could be done by retaining a married man, especially as this officer was actually willing to allow his wife to live away from his professional residence, so that his position might not be lost? Surely the Commissioners of the Board of Control should take action in this matter and see who is to blame—the committee or medical superintendent.

A spirit of antagonism against one's employers is to be deprecated, but it is not to be wondered that organisations are made to defend the victims of such lack of consideration and unjust treatment. The Association of Assistant Medical Officers might now be revived seeing that A.M.O.'s are back at their old work. The advantages of being married in the case of medical officers of asylums, who have to live among special environments and temptations, are so apparent that no further observations on the matter are necessary.

I am, Sir, yours faithfully,  
August 20th, 1919. A MARRIED A.M.O.

## Obituary.

CHARLES ARTHUR MERCIER, M.D., F.R.C.P. LOND.,  
F.R.C.S. ENG.,

CONSULTING PHYSICIAN FOR MENTAL DISEASES, CHARING CROSS  
HOSPITAL; LATE PRESIDENT OF THE MEDICO-PSYCHOLOGICAL  
ASSOCIATION.

WITH the death of Charles Mercier at Bournemouth, in his sixty-seventh year, medicine has lost one of its ablest dialecticians, whose erudition, wisdom, and humour enabled him to make valuable contributions in that dim borderland where psychology and insanity meet.

Charles Arthur Mercier was born in 1852, the son of the Rev. L. P. Mercier, and was educated at Merchant Taylors School. His family was left in poor circumstances on the death of his father, and he became a cabin boy, in which capacity he sailed to Mogador, and later a clerk in a warehouseman's office in the City of London. At this time, fortunately, he became in a position to follow his natural bent and study medicine. He joined the London Hospital Medical School, and from that school took the M.R.C.S. in 1874, the L.S.A. in 1877, and the M.B. Lond. in 1878. To these primary diplomas he subsequently added the higher medical and surgical distinctions, taking the F.R.C.S. Eng. in 1878, being elected F.R.C.P. Lond. in 1904, and being awarded the M.D. Lond., with gold medal in mental science, in 1905. At the London Hospital he fell under the influence of that master of scientific medicine, Hughlings Jackson, whose keen and intensive studies in neurology formed the starting point of his pupil's interest in the subject of psychology in a wide sense. At first a close student of Herbert Spencer, Mercier subsequently struck out a direction of his own, based on his personal work. He held posts of medical officer in two large public asylums, the Buckinghamshire County Asylum at Stone and the City of London Asylum, and after relinquishing these appointments he became for the greater part of his life resident physician at a private asylum. He made full use of his opportunities for a close study of lunacy, and from his personal daily work he evolved a philosophy of life, which he exposed with frankness and defended with tenacity. What proportion of the world Mercier considered to be a little mad it would be hard to say, but he was a very genuine friend to the insane. It was largely owing to his unceasing zeal that a Bill was introduced several times in Parliament to legalise the treatment of insanity in its early stages, and it is regrettable that he did not live to see what can hardly fail to be the full fruition of his and others' labours in the near future. The legal standing of the lunatic was his particular care, and he was a valuable member of the Medico-Legal Society, where his early contributions were of a highly interesting nature. Some of our readers may recall the discussion of a problem arising out of a paper by Mercier, and illustrated by a case tried at Stafford. It came out in that debate that the law had overlooked the possibility that a sane person might be prevented, by deafness and inability to read, from understanding the proceedings in a court of law. Mercier's equal facility on the medical and legal side of mental disease long served the Medico-Legal Society in good stead, while he himself thoroughly enjoyed his forensic excursions.

As a writer Mercier's genius found its particular expression. From his first contribution on a Classification of Feelings in *Mind* (1884) to his last work on "Crime and Criminals" (1918) he never wrote a slovenly sentence and never spared himself the most assiduous effort to make his meaning clear and precise to his readers. His "Text-book on Insanity," appearing in 1902, was the first comprehensive view of insanity in its practical aspects. Within a moderate compass, available to the student and practitioner of medicine, his logical mind delineated forms and varieties of insanity as types, with illustrative examples culled from his own abundant clinical experience. It speaks much for his mental fertility that this text-book appeared almost at the same time as his work on "Psychology, Normal and Morbid," which was largely responsible for making his name known as a writer in wider circles of philosophy. In this book he approached psychology from the subjective side, treating morbid conditions in the light of normal conditions working inharmoniously, and making no attempt to connect the manifestations of mental alienation with definite morbid lesions of the brain. The close and

accurate reasoning and the facility in the statement of abstract propositions which characterised all his later work were present here. In his last book Mercier turned again, as was his wont, to first principles. He proposed to discover the foundations upon which criminal law rests, so as to determine in what directions improvement was possible. His chapters on the prevention, detection, and punishment of crime are of great general interest, and his definition of crime as "due to temptation or opportunity, the environmental factor of stress, acting upon the predisposition of the offender, the inherent or constitutional factor," is a convincing example of Mercier's clearness of thought and absence of acquired prejudice. This able, useful, and original hook earned for him for the second time in succession the Swiney prize. He also wrote a book on logic, which failed to find acceptance.

Mercier revelled in argument, and for a time he may be better remembered as a dialectician than as a fine writer and a constructive sociologist. But the fame of dialectics is transitory, and, good controversialist as Mercier was, he certainly sacrificed points to a desire to score, and he allowed his wit to run away with his judgment. Often his nimbleness of brain led him beyond the position which could be taken up by strict logic. He had for many years been a serious invalid, and at no time lately would his death have caused any surprise. We have lost in Mercier one of the most sheerly clever men who ever adorned the ranks of medicine. And behind the cleverness lay a mass of solid learning.

WILLIAM ANGUS, M.D. ABERD., D.P.H.,

MEDICAL OFFICER OF HEALTH FOR THE CITY OF LEEDS.

THE untimely death of Dr. William Angus, M.O.H. for the City of Leeds and professor of public health in the University, cuts short a career of great promise.

William Angus was born in Aberdeen in 1884, and was a student there as well as at University College, London. He qualified in 1909 after obtaining many academic honours, including the Mather scholarship in medicine. For 18 months he held the position of senior assistant medical superintendent at St. Pancras Infirmary, London, and in January, 1911, began his public health work proper, being in succession assistant medical officer of health for Hertfordshire, for Ipswich, and for Leeds. In February, 1917, he became chief health officer for the city, and in June of the same year he volunteered for active service with the R.A.M.C., becoming A.D.M.S. (Sanitation), with charge of the sanitary arrangements in connexion with the 1st Echelon in Egypt. On returning to this country in February last he threw himself into the work of the organisations of which, apart from his official duties, he had been a moving spirit. Foremost among these was the Maternity and Child Welfare Scheme, for the organisation and development of which he was largely responsible. His efforts won a competitive shield for the best organised "Baby Week" throughout the country. He also took a keen interest in the organisation of tuberculosis relief measures.

One of his colleagues (J. J. J.) writes thus of him:—

"When Angus came to Leeds in 1913 he came full of freshness and vigour. He had been an athlete in his student days at Aberdeen University, and his carriage and bearing bore testimony to the excellence of his training. The uprightness of his body was an index of the uprightness of his mind. He was a true Scot—straight, clean, and honest, conscientious to a fault, firm to his convictions, and loyal to his friends. He said little, but what he did say he said with a directness and precision which carried conviction; he had no time for superfluity of speech. One reason for his success was the easy way in which he could grasp things and, when once within his grasp, retain them. He could snuff up a situation in a trice, and his conclusions were invariably correct. Like the sons of the North, he was something of a mystic, a dreamer, only in his case his dreams were not nebulous but very real things. He was a man of ideals, and his life and work in Leeds furnished him with scope enough for their development. In his public life Dr. Angus was imbued with the one idea of serving his fellow men faithfully and leaving the world and the city of his adoption the better for his life's endeavours. For himself he desired nothing, only to fill the niche allotted to him in the world and complete his appointed task in such a manner as to win the approbation of his generation."

And another (M. J. S.) adds:—

"A man of sterling and transparent honesty and high purpose, Angus combined in a remarkable degree the

qualities of the idealist and the man of action. The possessor of great executive ability and sound common sense, he impressed all with whom he came in contact by his breadth of vision and power of grasping the essentials of a situation. He was a man of few words, but those well chosen, cogent, and to the point. His clarity of expression is well exemplified in his admirable report, just published, on malaria in the Egyptian Expeditionary Force during 1918, a document of high scientific and historical importance. Of the quality of Angus's professional work it is impossible to speak too highly. All of it was done with energy and enthusiasm, and he would tackle the biggest and most difficult problems with the keenest possible zest and determination. In the academic sphere, as professor of public health in the University of Leeds, he was equally successful. He enjoyed to the full the confidence of his colleagues, and one felt that in these days of change and reconstruction Angus, the steady, wise, and clear visioned, was the right man in the right place."

Personally, William Angus was a most lovable man and a delightful companion, and his death leaves a gap in the circle of his friends which it will be impossible to fill. To his wife and two little daughters goes out at this time the heartfelt sympathy of all their friends.

#### SKENE KEITH, M.B., F.R.C.S. EDIN.

THE death of Mr. Skene Keith, which occurred on August 19th after a week's illness from pneumonia, follows closely on that of his brother, Dr. George Keith, who died last December from the same cause. With little outward show, Mr. Skene Keith achieved no small success as an operating gynaecologist, and his death will be felt as a loss over a wide circle. Both brothers inherited something of the diagnostic acumen and manual dexterity of their father, Dr. Thomas Keith, well known in his time as a pioneer of ovariectomy. Many years ago Mr. Skene Keith published his first hundred cases of ovariectomy, with a mortality of rather under 3 per cent., and his results improved still further as time went on. He came to London while still a young man and was appointed to the staff of the Samaritan Hospital, but returned shortly after to Edinburgh to assist his father, until both came to London at a later time. Mr. Keith's "Text-book of Abdominal Surgery" (1894) and his "Gynaecological Operations" (1900), the former in collaboration with his brother, Dr. George Keith, were his principal published works.

#### THOMAS TORKINGTON BLEASE, M.R.C.S. ENG., L.S.A. LOND.

Thomas Torkington Blease was born in Altrincham, Cheshire, on Oct. 4th, 1835. He was the son of Thomas Blease, L.S.A., who was born at Altrincham in 1804, and after qualifying practised there until his death in 1883. Father and son were together in practice for 27 years, then Mr. Thomas Torkington Blease carried on the practice for 21 years, when he in his turn was joined by his only son, who survives him. Mr. Blease qualified in 1856, after studying at the Manchester Royal Infirmary and the Pine Street School of Medicine, and also in London. He at once commenced practice in Altrincham and in 1858 founded the Altrincham Provident Dispensary, which later became, and still continues as, the Altrincham Provident Dispensary and Hospital. To this institution, of the success of which he was justly proud, he gave devoted service for more than 40 years. In May, 1869, he was appointed medical officer for the Altrincham district of the Bucklow union and held this post until August, 1912. For 45 years he was medical officer to the Great Central Railway Mutual Provident Society, and on his retirement in 1908 he was the recipient of an illuminated address from the members. He also held numerous appointments with other friendly societies. He most thoroughly approved of the principle of these efforts of the working classes to help themselves, and won the unbounded esteem of their members by the way in which he never spared himself in connexion with such work.

Until comparatively recently he enjoyed remarkably good health; when over 70 years of age no amount of night work seemed to make any difference to his ability to carry on as usual during the day, and by this infinite capacity for work he was able, while holding all the above appointments, to have for over 60 years, first in association with his father, then single-handed, and later in association with his son, an extensive private practice which alone was as much as most men could have done even for a much shorter period.

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BARNES, H. W., M.B., B.C. Cantab., D.P.H., has been appointed Medical Officer of Health and School Medical Officer for Yeovil (Somerset).  
GUNN, W., M.B., Medical Officer for the Wadebridge (Cornwall) District of the Bodmin Union.  
HAYCRAFT, GUY F., M.R.C.S., L.R.C.P., Honorary Ophthalmic Surgeon to the Walsall General Hospital.  
LANGLEY, GEORGE JOHNSON, B.S., M.D. Lond., Honorary Assistant Physician to Salford Royal Hospital.  
SMITH, R. WAYLAND, M.B., Ch.B. Edin., Senior Resident House Surgeon at the Royal Devon and Exeter Hospital.  
STURROCK, ALEXANDER CORRAR, M.A., M.D. Edin., M.R.C.P. Lond., Honorary Physician to Salford Royal Hospital.  
SUTHERLAND, R., M.B., Ch.B. Vtct., Temporary Medical Officer of Health for Chard (Somerset).  
Leicester Royal Infirmary: CROSEY, T. V., M.D. Lond., Honorary Physician; SLIGHT, J. D., M.D. Edin., and FOSTER, A., M.D. Edin., Assistant Physicians; LAWSON, R. S., M.B., Ch.B. Edin., F.R.C.S. Eng., Assistant Surgeon.  
Queen Charlotte's Lying-in Hospital: DAVIES, TREVOR B., M.D., M.R.C.P., F.R.C.S., Obstetric Surgeon to Out-patients; DEARNLEY, GRACE, M.D., Medical Officer to the Antenatal Department; WILLMORE, J. GRAHAM, M.R.C.S., L.R.C.P., Pathologist and Registrar.  
Certifying Surgeons under the Factory and Workshop Acts: DUNCAN, J. M., M.B., Ch.B. Aberd. (Ascot); DEVINE, J. A., M.D. Dub. (Newhaven); BAKER, J. R., M.D., B.Hy. Durh. (Tyne-mouth); BABST, E., M.B., B.S. Durh. (Wallsend-on-Tyne); LIBBEY, E. O., L.S.A., L.M.S.S.A. (Scarborough); PAYNE, R. W. (Lavenham).

## Vacancies.

For further information refer to the advertisement columns.

Aylesbury, Royal Buckinghamshire Hospital.—H.S.  
Barbados General Hospital.—Sen. Res. S. £300.  
Battersea General Hospital, Battersea Park, S.W.—Res. M.O.  
Birkenhead Borough Hospital.—Jun. H.S. £170.  
Birkenhead Union Infirmary.—Res. Asst. M.O. £300.  
Bridgend Urban District Council, Penybont Rural District Council.—Joint M.O. H. £600.  
Brighton, Royal Sussex County Hospital.—H.P. £100.  
Bristol Eye Hospital.—H.S. £150.  
Bristol General Hospital.—H.S., Obstet. O., and H.S. Also Two H.P.'s. £175.  
Burnley Union Workhouse.—Res. M.O. £400.  
Cambridge, Addenbrooke's Hospital.—Hon. Asst. P. and Hon. Asst. S. Cancer Hospital (Free), Fulham-road, S.W.—Two H.S.'s. £150.  
Cardiff, King Edward VII's Hospital.—Hon. S. and Hon. Asst. S.  
Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—H.S. £50.  
Chartham, near Canterbury, Kent County Mental Hospital.—Jun. Third Asst. M.O. £300.  
Chester Royal Infirmary.—H.P. £150.  
Chichester, Royal West Sussex Hospital.—H.S. £200.  
Derbyshire Royal Infirmary.—H.P. £200.

 St. Peter's Hospital for Stone, &c., Henrietta-street, Covent-garden, W.C.  
 Jun. H.S. £75.  
 Salford Royal Hospital.—Hon. Dent. S. Also Res. Surg. O., H.P.,  
 H.S., and Jun. H.S. £250, £200, £150, and £125 respectively.  
 Scarborough Hospital and Dispensary.—Two H.S.'s. £150.  
 Sheffield City Education Committee.—Sch. Dental S.'s. £400.  
 Sheffield Royal Infirmary.—H.S. for Ear, Nose, and Throat. £150.  
 South Africa, Mental Hospital Service.—Asst. P.'s. £380.  
 Southampton, Free Eye Hospital.—H.S. £150 to £200.  
 Southwark Borough.—Female Asst. M.O.H. £400.  
 Swansea General and Eye Hospital.—H.S. £250.  
 Uxterston, High Carley Sanatorium.—Asst. Taherc. M.O. £350.  
 University College Hospital, Gower-street, W.C.—Asst. S.  
 Wallasey, Victoria Central Hospital.—Hon. Ophth. S.  
 Wallasey General Hospital.—Female H.S. and Anæsth. £175.  
 Wills County Council.—Sch. Dentist. £350.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Inspectors under the Factory and Workshop Acts at Kilgough and Luddenden, Brigg (Lincoln), Darford (Kent).

THE Secretary of State for the Home Department gives notice that in consequence of the death of Mr. F. Wilson, one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 28, the appointment held by him is vacant. Mr. Wilson was attached more particularly to the Aberystwyth, Dolgelly, Llanidloes, Machynlleth, and Newtown County Courts. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Sept. 11th, 1919. Notice is also given that in consequence of the resignation of Mr. J. L. Russell, one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 12, the appointment held by him is vacant. Mr. Russell was attached more particularly to the Todmorden County Court. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Sept. 25th, 1919.

## Births, Marriages, and Deaths.

### BIRTHS.

BROOKS.—On August 31st, at Beaufort House, Grange Park, Ealing, the wife of Captain Ralph St. John Brooks, R.A.M.C., of a son.  
 HENRY.—On August 19th, at The Croft, Sandon-road, Edghaston, the wife of A. R. Henry, B.Sc., L.D.S., of a son (Richard Montagu).  
 LESLIE.—On August 27th, at a nursing home, the wife of Captain W. Leslie, M.C., R.A.M.C., of a son.  
 OSBORN.—On August 21st, at Sheet-street, Windsor, the wife of Dr. A. G. Osborn, of a son.  
 PORTEOUS.—On August 26th, at Drumsheugh-gardens, Edinburgh, the wife of W. J. Porteous, M.B., Ch.B. Edin., of a son.  
 STEPHENS.—On August 26th, at Fair Elms, Sandown, the wife of J. B. Stephens, M.B., B.S. Lond., of a daughter.  
 WHITEHEAD.—On August 24th, at Rougemont, Salisbury, the wife of Brian Whitehead, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

### MARRIAGES.

DEBENHAM—ARCHER-SHEE.—On Sept. 2nd, Leonard Snowden Debenham, M.B., B.S., B.Sc., to Anna, daughter of the late Martin Archer-Shee, of Bristol and Nailsworth, Gloucestershire.  
 ELLIOT—HAMILTON.—On August 27th, at St. Margaret's, Westminster, Captain W. E. Elliot, M.P., M.C., R.A.M.C., to Helen A. Hamilton, eldest daughter of Lieutenant-Colonel D. L. Hamilton, R.A.M.C. (T.).  
 EWENS—KELLEHER.—On Sept. 1st, Bernard C. Ewens, M.B. (late Captain, R.A.M.C.), to Mary, daughter of the late James Kelleher, D.L., Bengal Civil Service (retired), and of Mrs. Kelleher, Goderich, Ontario.  
 GARDNER—PONTON.—On August 21st, at All Souls Church, Langham-place, W., Humphrey D. Gardner, Captain, R.A.M.C., to Phyllis Ponton.  
 HUNTER—KEMPSON.—On August 21st, at the Chapel Royal, Savoy, Captain (acting Major) John Henderson Hunter, M.C., R.A.M.C. (T.F.), to Dorothy Kenelm, only daughter of the late Frank Kenelm and Mrs. Kempson, Kingsbrook House, Bedford.

### DEATHS.

ANGUS.—On August 23rd, at St. Cyrus, Scotland (very suddenly), aged 36, William Angus, M.D., D.P.H., Medical Officer of Health for Leeds. Interred at Aberdeen, August 25th.  
 CHEVERS.—On August 10th, at Southmead Military Surgical Hospital, Bristol, Major Herbert L. G. Chevers, R.A.M.C. (retired), aged 59.  
 FOX.—On August 16th, at Panyam, Nigeria, John Crofton, M.R.C.S., L.R.C.P.  
 HEWLETT.—On August 26th, at Andover, the result of a cycle accident, George Hewlett, Surgeon-Commander, R.N., retired.  
 HUMPHRY.—On August 29th, Reginald Humphry, M.R.C.S., L.R.C.P., of Nelson-road, Southsea, aged 67.  
 KAZANJIAN.—On August 10th, at Boston, Mass., following the birth of a daughter, Sophie, wife of Major V. Kazanjian, C.M.G.  
 KEITH.—On August 19th, at Bryanston-street, W., after a brief illness, Skene Keith, M.B., C.M., F.R.C.S.E., aged 61.  
 STEVENS.—On August 25th, at Gordon House, Bocking, Essex, Percy Richard Stevens, L.R.C.P. Lond., M.R.C.S. Eng., aged 61.  
 WRIGHT.—On August 28th, at Blakesley, Northants, Cyril Haworth Wright, M.B., Ch.B. Edin., D.P.H., R.C.P.S., aged 43.  
 N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### THE PERTSHIRE UNIT.

THE following interesting letter from Nish has reached us through the kindness of "J. G. F.," who has forwarded it to us "in the belief that it will prove of interest to readers who have served lately in Macedonia, particularly with the Serbian Units."

The Perthshire Unit, Serbian Relief Fund.

Nish, Serbia, July 25th, 1919.

It's hard to realise that it's almost 6 months since I left England, yet it will be on August 14th. Although my address says "Nish" I'm really 40 kilometres (25 miles) from that town, out at Prokuplje, which is slightly north-west from Nish. We are right off the railway line, which at first made us awfully cut off when the weather was bad. Now of course the road is dry, so cars come out to us oftener; so far I've not one of my own.

I've made a hospital: well it has been a job, but there is much satisfaction now in looking over an extremely good garden on to four large marquees each holding 14 beds, another of 12 beds and a long one-storied building which holds 22 beds. We have a funny little cottage not half bad now it's really clean and for the rest of the staff I've rooms outside. Although I've only 60 beds, there is much work here, as there is a very large out-patient department. This hospital supplies accommodation for, or rather I should say, meets the urgent needs of a good many villages, as well as this town with its 7000 inhabitants. When first we got here in the early days of March we at once commenced a soup kitchen from which 1600 were fed daily, also we distributed clothing. But this town itself has not suffered as much as the villages. In these the picture of misery is too awful. In view of the facts that I'm soon to begin a distribution of clothes in villages within a radius of 30 kilometres I've been by degrees visiting a good many to see for myself how things were and what the most pressing needs were. In one village, only 13 kilos from here, I found only 5 houses standing, where originally 65 stood; all the rest are in ruins.

The people there now live just in what was once the cowhouse below the level of the ground or else in shelters built against the steep mountain side with neither light nor ventilation. In one small room I was told 13 slept, all on a hard mud floor. In one corner there was some wood ash, so I knew they had had a fire, in fact I saw the small black opening in the roof, the only ventilation, and I wondered what chance there was for these poor people should one fall a victim to the all too prevalent disease—tuberculosis.

I asked why there was such crowding in view of the fact that the weather was so pleasant for sleeping out, but was told that wolves came into the village every night which made it impossible to sleep outside, in fact the few animals that the people possess are taken inside as well for fear of being lost.

Almost all the houses had had the furniture removed. The village I mention was one quite near the forest, right up towards a high mountain range. The people told me what an awful time they had had. Their men were mostly with the Comitadj, living for three years in the forests. The Bulgars occupied all the villages during the day and took everything they could find, but retired for the night, as they were too frightened to remain on account of the Comitadj. As soon as night came, down came the Comitadj, and the women gave them as much food as they had been able to conceal from the Bulgars. Here in Prokuplje the houses bear little evidence of war, except in one place where a bomb fell; also the Public Buildings are riddled with shot holes—here the Bulgars in occupation of the town had to take refuge when the Comitadj from the forests on the town came down and stormed the town. This they did just after the fall of Monastir (December, 1916) as they were under the impression that an advance was then to be made. They kept storming the Town Hall for two days and then the Bulgars, 480 of them, gave in; the Comitadj held the town for 15 days and then were driven out once more by German heavy guns which had been brought up. Then the persecution of the women began; they were clad with knives, handed with hot irons and tortured in every possible way: the Bulgars demanding to be told where the Comitadj had gone. I have seen many of these women at our Dispensary with great sores all round their sides and down their backs, and in one case a woman came with an awful chest just one mass of holes, from which pus was pouring; the remaining evidence of when she had been prodded by a bayonet! These things must be seen to be believed. Beyond this lovely garden of mine, which we just made out of a rough field, I look across open country for a little way and then a glorious range of mountains rises: on the slope of a nearer one, just where now a cornfield ripens, 30 or 40 people of all ages and both sexes were done to death every night for trumped up trivial offences! Such is war!

Many men have found their families and many of the older soldiers have been demobilised and come home; but then I've met others who say they have been to their villages and have found just a heap of stones to show where once a comfortable home stood and that no trace of the family or word of their fate can be found.

I'm most tremendously interested in it all and only wish one could do more and work more rapidly, but I suppose every little helps. Just now in this place we've a typhoid epidemic, but during two weeks we have only had 14 cases. I've had to see to the disinfecting of the houses where cases have developed and have distributed soap and urged cleanliness. I work here entirely with a Czech Doctor and his partner, also a Czech. The senior is quite a capable man, he speaks only French, the other German; however, we jog along; no English doctor of course. We get many cases of malaria, but I've never once seen a mosquito. We all have nets up, but have so far not slept under them. I'm afraid this is a very long letter, but my pen runs away with me, because I'm so interested in my subject. ....

This interesting account provides ample evidence of the terrible sufferings which the poor country folk of stricken but victorious Serbia are undergoing. Clearly there is at

the moment a great demand for help, and the demand will last for some time, and it should not fail to appeal to all of us at home. The devotion to the Serbian cause which our women have shown should stimulate a material response.

#### THE CHILDREN'S COUNTRY HOLIDAYS FUND.

Sir Horace B. Marshall, the Lord Mayor of London, has issued an appeal on behalf of this Fund, through the agency of which it is hoped that over 20,000 London children will be given a fortnight's holiday in the country. A large number of poor children have already been sent away for a holiday, but there are hundreds more on the list, and the Fund is spending more rapidly than it receives. Additional donations are urgently required to prevent undue depletion of the reserve fund. Cheques made payable to the Fund should be sent to the Secretary, C.C.H.F., 18, Buckingham-street, Strand, W.C.2.

#### THE FOOD EDUCATION SOCIETY.

THE activities of the Food Education Society (honorary secretary, Mr. C. E. Hecht, M.A., M.C.A., Danes Inn House, 265, Strand, W.C. 2) are to be extended and the co-operation of allied societies has been successfully invited. It has been decided by the society to hold a conference in Manchester in 1920 on the lines of the Guildhall School conferences of 1912 and 1913, in which problems connected with the teeth figured prominently. (See "Our Children's Health at Home and at School" and "Rearing an Imperial Race.") A strong and representative committee is in course of formation. Steps are also being taken to constitute committees in Birmingham and other places, so as to arouse interest in, and secure adequate representation at, the conference and to arrange for a local campaign. Invitations will be issued on a large scale throughout the United Kingdom. A draft programme of the conference, with tentative suggestions for a local campaign, which include a travelling exhibition, and further particulars will be sent on receipt of a stamped addressed envelope, if application be made to Mr. Chas. E. Hecht at the offices of the society.

#### LEFT- AND RIGHT-HANDED COUCHES.

To the Editor of THE LANCET.

SIR,—The modern couch sold as part of a "suite" has the head at the left end when the back rail is against the wall. The effect of this is that the occupant naturally reposes on his right side. Couches many years ago used to be made also with the head at the right end, so that the occupant would lie on his left side. This kind of couch, I find, is seldom made now, and I have a faint recollection that it was condemned because lying on the left side after a heavy meal brought on, or was supposed to bring on, indigestion or palpitation, or something worse. I am rather curious to know whether that was the real reason for the abandonment of such couches, which, I think, are called "right-handed" couches. Perhaps some of your readers know and could inform me. I am, Sir, yours faithfully,

August 25th, 1919.

LAYMAN.

#### PHYSICAL PROGRESS AND MENTAL RETROGRESSION.

THE testimony of all military medical officers is clear upon one point—namely, that although the physique of the last lot of recruits for the fighting line, called up about 1915-1916, was poor, yet the physique of those who had attained the age of 17 to 18 in 1917, and were then called up for training, was extraordinarily good. This fact was due in great measure to their having been well fed from the age of 14 or 15, i.e., from the beginning of the war. Their parents had had more money owing to increased wages, and had spent it wisely in giving the children better food. The same improved development due to the same factors may be noted in the children who are to-day between 11 and 13. Physical development, however, is not everything, as two paragraphs in the same issue of the *Times* showed one day last week. One of these deals with the case of a boy, aged 13, who showed a friend a small jar, saying, "It is rat poison. I am going to take it for the sake of a girl because she does not like me." He took it and eventually died from phosphorus poisoning. Evidence was given that "he was a boy for girls," and the father said that his son was strong willed and well developed physically. He had thought about telling his son concerning matters of sex, but had not done so. The other paragraph relates the familiar story of a window in a train being broken by a stone, the passengers in the carriage being covered with glass. It was presumably thrown by a boy, the fusion of the sexes has not yet got to the point of producing a girl who can throw a stone. Throwing seems to be a natural impulse in boys, or rather, we should say, the desire to hit a moving body with a missile is universal among them, but the impulse should be guided in the direction of wickets rather than trains. The suicidal youth seems to have been impelled by sexual impulses, which are normally strong and also

unbalanced at the time of puberty. Moreover, the conditions of the last four years have undoubtedly tended to laxity in sexual matters and also to opportunity. It is to be feared that physical development has not gone hand-in-hand with instruction as to the necessity for keeping the bodily functions under control.

#### CURRENT SEXUAL DECORUM.

*Qui s'excuse s'accuse.* The number of pens at work lately (when there have surely been plenty of other things to put in the journals) defending phenomena like new styles of dancing, like mixed bathing followed immediately by much "jazzing," like the present fashion of scanty feminine dress both by land and sea, sufficiently demonstrates a change in public conduct in the matter of sexual decorum. Whether that change arises from a spirit of mere licence and rebellion, or from a new moral evaluation, is uncertain. Probably—ætiology being ever complex—both motives operate, with many others in addition. What is invariably mentioned as a cause when this subject is discussed is reaction from the strain of war; but since the change spoken of has been noticeable, though not quite so prominent as now, any time this last two or three years, if not for longer, it cannot play a great part. What lies far deeper is the lowering of moral tone brought about by war itself, for great dangers, as Bacon remarks, demand great delights, and the spirit of the soldier is in essence the spirit of the adventurer. War brings excitement, too, and excitement, especially in women, easily runs over into sexual manifestations. Again, women, upon whom society, as well as Nature, imposes a stricter code of morality, have been almost from the beginning of the war in a position of greater social and economic independence than formerly. It would be incorrect to lay exclusive stress upon factors like these, which a conventional moralist would call unfavourable. For the progress of human culture is perhaps showing that the indispensable barriers which Freud has called "shame, loathing, and morality" are not in their proper positions. They may, even now, be too narrowly set, may make libertines of too many.

#### TENACIOUS ADVERSARIES.

Mr. Aylmer Maude, a well-known authority on Russian affairs and literature, and the author of a life of Tolstoy, is responsible in the columns of the *Westminster Gazette* for the following story:—

"A curious instance of extreme tenacity of life among the lower races was mentioned to me by Major R. Black, R.A.M.C., now surgeon to the Divina Force, and before the war a well-known practitioner in the Midlands. The case occurred at Bakaritsa. Two friends of Mongolian origin, in a labour battalion, played cards, and A won more than B liked to lose. Thereupon B got a sharp axe and drove it through A's skull and about 1½ in. into his brain. A was taken to hospital, where Major Black trephined him and repaired his brain. Next day A demanded his usual rations, and wanted to get up and go home to settle accounts with his friend. This was not allowed, but meanwhile B had been arrested, and, not wishing to submit to the Courts of the Western Barbarian, he hanged himself, and, after a period variously estimated at from five to ten minutes of suspension, was cut down. The surgeon was again sent for, and found the Russian attendants administering artificial respiration to the man at the rate of about 300 per minute, and nearly played out by their labours. This he slowed down to about 20, and after half an hour the man revived and was taken to the hospital ward his friend was in, as no bed was available elsewhere. On seeing him A became extremely violent, and it required six men to hold him down and prevent his exacting summary vengeance on B, who was still only semi-conscious. However, B, too, made a remarkable recovery, and half an hour later it took 12 men, six to each of the combatants, to prevent the two patients from fighting. Huge and repeated doses of morphia had no effect on either of them, but by arranging a bed in a separate ward for one of them murder was avoided, or at least deferred."

Mr. Maude, who is working on the Divina front, gives a satisfactory account of the health of the troops.

#### "STAMMERING AND VOICE DEFECTS."

To the Editor of THE LANCET.

SIR,—Will you grant me sufficient of your valuable space to make a comment on Miss Mabel Oswald's paper on the above subject in your issue of August 23rd? Miss Oswald is mistaken in saying that "stammering and functional voice defects have until recently been looked upon as unfortunate disabilities, and no real scientific attempt was made thoroughly to deal with such cases, and hence there was no recognised cure." In 1892 my father, the late Emil Behnke, was invited to address the British Laryngological Association on this subject, to demonstrate cases, and to explain his method. This body of experts accepted his system for the treatment of stammering and speech defects as being thoroughly scientific and sound, and their opinion has been endorsed and maintained by the medical profession in general in the years that have elapsed. His works on the subject, together with those of my mother, the late Mrs. K. Behnke, are recognised text-books.

I am, Sir, yours faithfully,

KATE EMIL BEHNKE.

Earl's Court-square, S.W., August 26th, 1919.

## THE VALUE OF MEDICAL SERVICE.

THE City Life Assurance Company, Limited, 6, Paulstreet, Finchbury, London, E.C., possess the Medical Examiners' Nomination Form reproduced below, and have endorsed it for the inspection of one of our readers who applied for the medical fee of £2 2s. :—

## SCALE OF FEES.

For Assurances up to and including £50, 2s. 6d.	These Fees refer to Industrial Proposals only.
For Assurances exceeding £50, 5s. 0d.	
For Assurances up to and including £50, 5s. 0d.	These Fees refer to Ordinary Branch Proposals only.
For Assurances up to and including £200, 10s. 6d.	
For Assurances exceeding £200, £1 1s.	

MEDICAL EXAMINERS' NOMINATION FORM: QUESTIONS TO BE ANSWERED BY THE MEDICAL EXAMINER.

Questions.	Answers.
1. Should the Directors decide to appoint you as Local Medical Examiner, will you undertake the usual duties connected therewith and accept the Fees above enumerated.	
NOTE.—In order to save the remittance of individual sums from time to time the Medical Fees will be paid by the Company Quarterly.	
2. What area is covered by you in connexion with your present practice?	
3. Please name the principal town and villages so covered. If occasion arises are you prepared to visit the proposers at their residences?	
4. Are you at present acting as Medical Examiner for any other Life Assurance Company. If so, please mention the Office or Offices represented.	
5. Are you in any way interested in the Company, either as a Policyholder or Shareholder? If not, is it your intention to become so interested?	

NOTE.—The Directors desire it to be distinctly understood that this nomination carries no guarantee as to the number of cases to be submitted for examination or remuneration to be received, and the Directors do not hold themselves responsible for any promise, verbal or otherwise, made by the Company's representative. Any application for shares, policies, &c., made by any Medical Officer must be made in the ordinary course of business, as the shares or policies applied for will be dealt with on this understanding.

## THE COOLIDGE DENTAL RADIATOR TUBE.

THIS dental radiator tube has been designed for the purpose of making radiographs of the teeth and jaw, and is not intended for general radiographic work. An important feature of the radiator tube is that it is self-rectifying and can be used directly across the terminals of either an induction coil or a high-tension transformer without the necessity for any auxiliary rectifying device, whereas the universal Coolidge tube must be used on rectified current. The disposal of the cathode and anode gives the following advantages, it is stated, for dental work: (1) the rays are emitted from the tube in a line with the axis of the anode, rendering manipulation and adjustment easy; (2) the cathode circuit is grounded, so that there is only one high tension wire connected to that part of the tube farthest from the subject; and (3) it is possible to reduce to a minimum the distance between the film and focal spot by which satisfactory radiographs of the teeth and jaws are obtained with comparatively short

exposure. Further details in regard to the advantages and conveniences of this special dental radiator X ray tube are furnished by the British Thomson-Houston Co., Ltd., of Rugby and 77, Upper Thames-street, E.C.4, who are the patentees.

## THE RANYARD NURSES.

THE annual report of the Nursing Branch of the Ranyard Mission for the year ending Dec. 31st, 1918, shows that their work among the sick poor has been carried on steadily under difficult conditions. The society is one of the oldest of the Voluntary Nursing Associations, having been founded in 1868 as an off-shoot of a mission to supply Biblewomen to the poorest and most neglected quarters of London. The Ranyard nurse attends patients of any denomination and those only who are under a doctor's care. She must be fully trained, and then undergoes a further period of six months' work under an experienced sister at the Central Hostel, 25, Russell-square, W., before she is allocated to the London district, where she will eventually reside and work. The staff, when complete, comprises 84 sisters and nurses, whose zeal and energy may be estimated by the fact that 11,853 cases were nursed during the year 1918. We are glad to note that the nurse's working day averages eight hours only and that night work is discouraged, also that the holiday conditions are good—five weeks a year and a day a month. The estimate of £130 a year for the equipment and maintenance of each nurse hardly suggests a lavish scale of remuneration under present conditions, but it must be remembered that the main source of income is voluntary contributions, and the balance-sheet already shows a deficit of £1584 for the nurses' fund. We trust that public support of this excellent society will be generous enough to warrant an increase of payment to its staff as well as an extension in its sphere of work.

J. F. T.—A coroner has great latitude in holding an inquiry as to the cause of death, and, where a suicide is seen to have been precipitated by the act of another, most coroners would take serious cognisance of the fact.

## Medical Diary for the ensuing Week.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &amp;c.

LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton and others:—

MONDAY, Sept 8th.—4.30 P.M., Lecture XI.—Conditions Simulating Dyspepsia. (Dr. Hutchison.)

FRIDAY.—4.30 P.M., Lecture XII.—The Differential Diagnosis of Medical from Surgical Dyspepsias. (Dr. Hutchison.)

## Communications, Letters, &amp;c., to the Editor have been received from—

THE  
Chadwick Lectures

ON

THE PROBLEM OF HYGIENE IN EGYPT.

*Being Three Lectures delivered at the Summer Session, 1919,*

BY ANDREW BALFOUR, C.B., C.M.G., M.D.,

DIRECTOR-IN-CHIEF, WELLCOME BUREAU OF SCIENTIFIC RESEARCH;

LATE PRESIDENT, EGYPTIAN PUBLIC HEALTH COMMISSION.

LECTURE II.—THE SOLUTION OF THE PROBLEM:  
PAST AND PRESENT.

In our last lecture we considered a number of the more obvious causes which go to make up the problem of hygiene in Egypt. There are, however, others equally important though less apparent to the mere onlooker, which are best discussed along with the schemes that have been evolved for dealing with as difficult a proposition as a sanitarian was ever called upon to face.

THE SHARE OF THE CENTRAL GOVERNMENT.

For the benefit of those not familiar with the Orient it may be well, in the first place, to furnish some explanation of the predominant share which the Central Government has always had to play in these schemes and which, as you will find, has been allotted to it in these lectures, so far as the perfecting of its machinery is concerned.

In England health reform is pressed upon the Government by the public; the movement originates amongst the more intelligent and more active members of the community; it is explained in the scientific journals, discussed in reviews and the public press; books are published, societies formed, lectures and public speeches delivered, deputations to Ministers arranged. By all these means the public is aroused to the necessity of action and, through Parliament, pressure is put upon the Government to introduce legislation. When at last legislation is obtained it is largely the public, through local bodies, societies, the medical profession, and public-spirited individuals, which sees to its enforcement; and it is again public opinion which demands its extension and amendment. The rôle of the Government lies chiefly in its sympathetic assistance and in helping to obtain uniformity in administration.

How very different in Egypt! There the position is entirely reversed. Public opinion initiates nothing, demands nothing, enforces nothing. If, therefore, any advance is to be made in public health it is the Government which must call attention to the necessity of reform, the Government which must initiate and press through proposals, the Government which must try by education to overcome the inevitable opposition caused by the natural conservatism of the population. From the public little more can be expected than passive acquiescence in the proposals of the Government. A Central Government, therefore, strong enough on its health side to influence and arouse public opinion, to stimulate lethargic local bodies, and to demonstrate the usefulness of health measures by successful experiment, is the prime necessity of health reform in Egypt.

PIONEERS IN SANITARY REFORM.

The courageous person who first undertook the work of reform was Clot Bey, a Frenchman, who in 1825, under the enlightened rule of the great Mehemet Ali, established a Board of Health, which was chiefly concerned with providing means of treatment for sick and wounded civilians. This speedily led to the founding of a School of Medicine and Pharmacy and also of a Maternity Hospital, but it was not until 1845 that a Civil Sanitary Service was inaugurated in addition to the existing Military Sanitary Service, which dated back to 1820.

About this time it would appear that considerable activity was displayed in abating nuisances. Vaccination was largely practised and the registration of deaths was efficient. Indeed, a European Commission reported favourably on the manner in which the sanitary department was conducted, a fact well worth remembering by those pessimists who are inclined to say Egypt was always backward and

No. 5011.

will ever remain so. It is significant that in those days, for a period of more than 12 months, no case of plague or cholera occurred in the country.

Unfortunately, this satisfactory state of affairs did not continue, and at the time when Great Britain undertook to rectify and control the administration of the country sanitary matters were in a lamentable condition. The causes are not far to seek, and as some of them are operative in the problem of to-day they may be briefly noted.

The lethargy of the East played an important part; corruption, with the inevitable cry for backsheesh, was rampant; ignorance, indifference, and lack of recognition of all that a sound and energetic sanitary policy stands for exerted a baleful influence. In addition, the finances of Egypt were in a most parlous condition, and there was actually very little money available for health measures. In those days, also, fanaticism was more powerful than is now the case and it was difficult to remedy the state of the mosques, which was often deplorable and afforded every facility for the spread of disease.

THE DEPARTMENT OF PUBLIC HEALTH.

In 1883 Mr. Clifford Lloyd created a Department of Public Health, and its first director was one who, in later days, delivered the Chadwick lectures with much acceptance, Dr. F. M. Sandwith, a man who ever placed duty before self and who, as Lord Milner says, "was got rid of by a rather ignoble intrigue due to the excessive zeal which he had shown in the dismissal of corrupt subordinates." Sandwith, however, set the sanitary ball rolling, and though its pace slackened a fresh impetus was imparted to it when Rogers Pasha, now Sir John Rogers, assumed control. He did a great deal for sanitation in Egypt, and his successor, Sir Horace Pinching, carried on the good work. It is unnecessary to enter into particulars as regards the various schemes put forward and completed during the period when these two able administrators fought disease and death in Egypt. Our theme is the problem at the present time for, despite all they accomplished, they were very far from attaining anything like perfection, and those who followed them found plenty to do and left plenty to be done. At the same time, it is necessary to note that the cause of hygiene was helped indirectly, but very effectually, by the manifold reforms carried through in other departments of the Government service. The fact that Egypt was rescued from bankruptcy and became financially prosperous aided sanitation, the spread of education helped it in large measure, the great development of public works, and especially of road-making, water-supply, and drainage schemes, assisted enormously; in other words, sanitation shared in the benefits attending the general quickening, as must ever be the case. It is essential that the hygienist should possess a spirit of sweet reasonableness and recognise that money expended on other services than his own may often be regarded as chinking in the sanitary coffers, though I admit it is not always easy to cultivate so philosophic a spirit, and that too much complacency in this direction is strongly to be deprecated.

*Shortcomings of the Administrative Scheme.*

Bearing all these points in mind, and remembering that lethargy, corruption, ignorance, indifference, and intrigue are always likely to hinder sanitary progress in Egypt, as indeed they do in other countries, let us see in what directions the lately existing scheme of health administration—a scheme, be it noted, admirable in many respects and the outcome of years of experience and labour—fell short of the ideal and thereby contributed its quota to the causes which we are considering.

In order to do so it is necessary to discuss the scheme itself, and I direct your attention to the graph. (Graph 1.) As I have indicated, this scheme, or rather its execution, has gone a long way towards solving health problems in Egypt, and in its discussion attention will be drawn not only to its shortcomings, such as they are, but to its virtues, while points which may be obscure to those unfamiliar with the land of the Pharaohs will be elucidated so far as this is possible in the time at our disposal.

It will be seen that the Department of Public Health is merely a section of the Ministry of the Interior. It does not, so to speak, stand on its own legs. In "Modern Egypt" Lord Cromer devotes a chapter to the Interior and a subsidiary chapter to its three sub-departments. These are;

(1) prisons; (2) slavery; (3) medical and sanitary administration. There in a nut-shell you have one of the chief causes of the problem of hygiene in Egypt—lack of adequate and fitting status for the organisation that controls the factors governing the health of the nation.

#### *Subordinate Position of Sanitary Administration.*

One need not feel surprised that so notable an administrator as the late Lord Cromer was content with such a situation, was satisfied, or apparently satisfied, to class a great sanitary administration along with the sections of Government which look after prisoners and slaves. Lord Cromer belonged to a school which was not greatly concerned with health problems, save when waves of epidemic disease disturbed their peace of mind and the well-being of the community. Though by no means indifferent to medicine and hygiene and a good friend to the scientist, he perhaps scarcely realised the full significance of sanitary work in such a country as Egypt. I am quite certain he was infinitely more interested in Greek odes than in the pathogenic protozoa. Small blame to him. The day he represented is only now passing and it is passing slowly and with some reluctance. The medical profession itself is largely the cause of a conservatism which has hindered progress in hygiene, which has obscured the truth enshrined in Emerson's famous dictum, "The first wealth is health." The Faculty from time immemorial has been much more interested in the cure than in the prevention of disease, though, to its honour be it said, medicine is the profession above all others which cuts its own throat, which has always endeavoured to efface itself by following an unselfish tradition. But it is not only the clinician who, by indifference and lack of interest, has put his spoke in the sanitary wheel. The hygienist himself has too often been to blame, for how often has he asked for impossible things in an impossible way! His outlook has frequently been narrow, and it is no wonder that men like Cromer, who were accustomed to take a wide survey of life and of affairs, who had to weigh the claims of many applicants for money, and who, in addition, could scarcely be expected to appreciate fully how the increase of scientific knowledge had placed new and effective weapons in the hands of the sanitarian—it is not surprising, I say, that such men were a little apt to be suspicious of the enthusiastic reformer whose constant cry was that if he only got the funds he would achieve hygienic miracles.

The difficulties of the administrator in this respect are well set forth in the concluding chapter of that very interesting book by Dr. Malcolm Watson "Rural Sanitation in the Tropics." Therein he quotes the very words of the famous Egyptian Pro-Consul to good effect. It is, however, at last being understood that the welfare of a nation is closely bound up with the health of its people. Nowhere is this more true than in Egypt and nowhere is there a greater necessity for establishing a Ministry of Health. In this connexion let me read you a portion of a valuable memorandum on the subject by Dr. Cyril Goodman, late Assistant Director-General of the Egyptian Public Health Department, and one, truth to tell, who is much better qualified to deliver these lectures than I am, for he knows Egypt intimately and has done much to guide her health policy along sound and practical lines. He says:—

"As there is no public opinion in the country demanding health reform the whole of the driving force in favour of health measures must come from within the Government itself, or rather that part of the administration charged with public health duties. The progress attained is directly proportional to the influence which can be brought to bear upon the Government.

"As at present constituted the Department of Public Health has no direct influence upon the policy of the Government; it is represented neither upon the Council of Ministers nor upon the unofficial Council of British Advisers which with the High Commissioner go to make up the somewhat informal system of government in Egypt. The High Commissioner, except in so far as he is controlled by the Foreign Office, is possessed of supreme authority in so far as he cares to exercise it, but the representative of the Public Health Department has no right of access to him to press forward public health measures or to oppose measures detrimental to the health of the country.

"The Public Health is a subordinate Department classed with and often below the Customs, the coastguards, the Public Lands and the Survey Departments, which, however important in themselves, have very little concern with the public policy of the country. The result of this system,

or lack of system, is, as might be expected, a reign of disorganisation and misunderstanding. No opportunity is ever offered for the consideration of the health problem as a whole; lack of co-ordination between the various departments has led to conditions injurious to health which might have been easily remedied at the outset; individual public health measures are presented and pressed forward second- and very often third- or fourth-hand or not presented at all—killed or mutilated for some unknown reason by some unknown official of the superior hierarchy; measures with a strong public health bearing are discussed and agreed to without consultation of the department, which is left with the choice between silence and a belated and irritating protest. In short, the position of the department is very much that of an indignant subscriber whose only resource if he disagrees with the policy of his paper is to write a letter of protest which his editor may or may not insert."

#### *The Burden of Petty Detail.*

This is a serious indictment of the Government machinery, but I believe it to be fully justified, and I should say that this cardinal fault of lack of status is the chief of those more obscure causes which to-day render the question of health in Egypt as paradoxical as is the country itself.

In the past the Director-General has been burdened with petty details, a state of things which has tended to prevent him devoting sufficient attention to larger questions of policy and to the bearing of scientific discovery and progress on the affairs of his department. No separate section of medical intelligence has been available, and though, as will be seen, the Director of the Public Health Laboratories has ably filled the post of technical adviser in addition to his other duties, it is essential in these days of rapid change and widespread activities to have a properly organised bureau of information attached to every large department of hygiene. Egypt has suffered from the want of such an institution, and there has also been an absence of means for enlightening both Government officials and the public generally as to the nature and prevalence of preventable disease and the measures which have been and should be taken to combat it.

#### GROUPING OF SANITARY ADMINISTRATION.

Turning again to the graph and the Central Administration, we see that there are four chief sections of work, each controlled by a director. These are the sections dealing respectively with general sanitation, with hospitals, with ophthalmic hospitals, and with epidemics. It is necessary to consider them briefly in detail.

##### *I. Section of General Sanitation.*

Probably nobody but the director of Section I. has any real conception of the multifarious duties which fall to his share and the difficulties with which he is constantly beset. These difficulties, though largely due to the presence of the Capitulations, the state of sanitary law in Egypt, and in some instances to the flatness of the land, its water-logged condition, and the comparative scarcity of fuel, are also caused by an overloading of the section with matters which should be dealt with elsewhere. As a result the ill-effects arising from a chronic paucity of staff are intensified. For example, a great deal of the work concerned with cemeteries is, strictly speaking, not sanitary work at all, and should be relegated to the State Domain Administration or at the present time to the Survey Department. Later on, when local self-government has become a power in the land, as must needs be the case, the municipalities and village councils will doubtless assume control of the cemeteries in their respective districts. Anyone versed in public health administration will wonder why the words "medico-legal work" appear on the list of subjects classed under general sanitation, and no one not conversant with Egypt could read the riddle. It is no use saying more about the matter here, for the question is intimately bound up with the duties of the Markaz doctor, and will be considered when we discuss the rôle which that indispensable person plays in the provincial organisation.

Prostitution figures in the list, possibly with more reason, for at last, at long last, the nations are beginning to understand all that the results of prostitution cost them in the way of expense, inefficiency, wrecked homes, disease, degradation, and death. Still, prostitution is so intimately bound up with venereal clinics and hospital treatment that its sanitary control is undoubtedly better exercised elsewhere than in the company of offensive trades, insanitary buildings, drains,

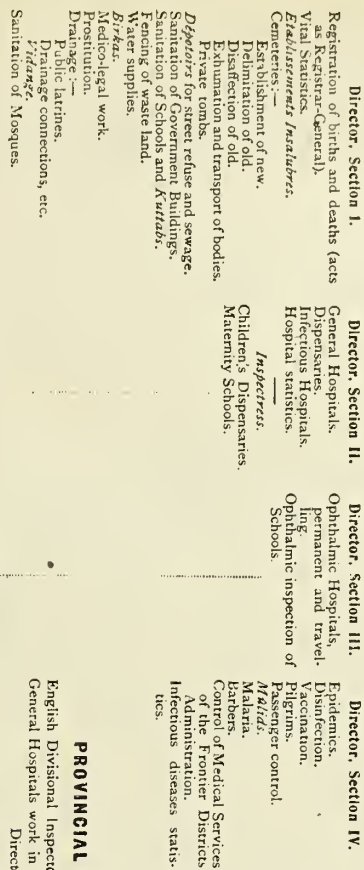

**PRESENT ORGANIZATION OF  
THE DEPARTMENT OF PUBLIC HEALTH.**

**CENTRAL ADMINISTRATION.**

GRAPH No. 1.

MINISTER OF THE INTERIOR.  
UNDER-SECRETARY OF STATE.  
DIRECTOR-GENERAL.  
ASSISTANT DIRECTOR-GENERAL.

Discussion with Director-General of matters of general policy of Department. Legal questions, drafts of laws, regulations. Departmental Orders, instructions, circulars, personnel questions, control of Departmental correspondence, Health Offices, prints and publications, stationery, permits to practise the medical and allied professions, Budget, Stores questions, Pharmacy questions and law, Cairo Scavenging and Watering Service, Cairo and Alexandria water questions.

**PROVINCIAL ORGANIZATION.**

English Divisional Inspectors who inspect all sanitary and General Hospitals work in the Provinces and report to the Director-General.

Inspector of Ophthalmic Hospitals.

Hospital Medical Officers and *Hakimas.*

Medical Officers of Health (of Cairo and Port Said) or Health Inspector (Suez and Damietta) of Governorates.

Quam Medical Officers in Cairo.

Barbers and *Diyari* in Villages attached to Governorates.

Mudirya Health Inspectors.

Special Epidemic Staff, disinfectors and rat-catchers.

Markaz and Outpost Medical Officers.

**WORK OF MARKAZ DOCTOR**

1. Infectious diseases.
2. Medico-legal examinations and reports.
3. General Sanitation.
4. (a) Inspection of Schools and *Kutabs.*
5. (b) Mosques' water system inspection.
6. (c) Sanitary reports on Government Buildings.
7. (d) Inspection of regulation of water intakes.
8. (e) Street cleaning.
9. (f) Slaughtering sites.
10. (g) Enclosure of waste lands.
11. (h) Inspection of *Wadys* for town refuse and loose contents.
12. (i) *Establishments Insalubres.*
13. (j) Disinfection.
14. (k) Vaccination.
15. (l) Control of registration of births and deaths.
16. (m) Prostitutes' examination where no hospital exists.
17. Cemeteries:—
18. Disinfection of old.
19. Exhumation of bodies.
20. Private tombs.
21. Public Health Inspectors on Local Commission.
22. Contraventions against the law regarding the practice of medicine, etc.
23. Pilgrims.
24. *Passenger control.*
25. *Examination of sick Government employees.*
26. Examination of *Chaghyrs.*
27. Inspection of deaths (uncertified).

Barbers and *Diyari* in Villages.

Vaccination.  
Inspection of Deaths.  
Registration of births and deaths is done by *Umdahs* and *Sarrafs*.

water-supplies, conservancy arrangements, and all the various matters which are sometimes for the sake of convenience, and not too inaptly, classed as nuisances. A possible objection to the use of this term may, however, be found in the fact that the harassed director of this section would often gladly extend it to include officials of the Ministries of Finance and Justice, who, possibly through no fault of their own, are brought sharply into conflict with him.

It is undoubtedly along the lines mentioned in this section that there has been the least progress in the past, and it is probable that general sanitation presents the most difficult of all the problems which have to be solved. The hygiene of the village, of the native quarters in the cities and large towns, the destruction of flies and mosquitoes, the control of food, the sanitary regulation of buildings are all included in this part of the health campaign and, as has been hinted before, it is no easy matter to hustle the East.

### II. Section of General Hospitals.

Hospitals, except those for infectious diseases, do not usually come under a public health administration, but you will see that Section II. embraces general hospitals, dispensaries, and maternity schools. The department whose work we are considering would probably in other countries than Egypt be termed the Department of Medical Services, for it is concerned with all matters affecting health. It is, I think, to the credit of those who christened it that they gave it a comprehensive title and one which brings prominently into notice the hygienic side of the work. It is not, however, the best name. That, let us hope, will soon be applied and will entail a radical change converting the department into a ministry—a Ministry of Health.

Most of the general hospitals under the Public Health Department are satisfactory, but there are not enough of them. This is specially true in the case of the larger provincial towns. The hospital is no longer looked upon with dread and suspicion. Not so long ago most of the lower class Egyptians certainly believed that a suitable hospital motto was: "All hope abandon ye who enter here," but happily that day is past and now the cry is for more beds and yet more beds. Hospitals, however, cost money and there's the rub! The Central Treasury has not a chest of bullion like the widow's cruse, and yet money must be found. Here, then, is another problem, the only solution of which lies in the establishment of local self-government and local taxation; measures still in their infancy in Egypt but capable of great development.

When this occurs it will be possible to provide more permanent hospitals for infectious disease. These are badly needed, for whatever the future may have in store, it will be long before communicable disorders cease to be one of the plagues of Egypt, and though certain of them are, perhaps, best treated in emergency hospitals others require the comfort and hygienic surroundings associated with a permanent building. Both classes of hospital suffer to some extent from a lack of sufficiently frequent and skilled inspection. Dispensaries, and more particularly children's dispensaries, are amongst the most useful health institutions in Egypt, but there are far too few of them, especially considering that the provision for children's beds in the general hospitals is inadequate. There is also a lack of beds for gynaecological cases, and a great need for women's outpatient clinics throughout the country. You will see that maternity schools figure in the list. There are six of these, but that number is not sufficient. Owing to the harem system in Egypt, the proportion of maternity cases attended solely by midwives is very high, amounting almost certainly to over 90 per cent., and at present the training of the dayas or midwives is most defective, while the mumarridas, though well trained in nursing and midwifery at the Kasr-el-Aini Hospital in Cairo, have, partly as the result of having long been called hakimas, been in the habit of practising medicine as well as midwifery, and certainly require to have their duties defined and their activities controlled. There is good reason to believe that they often pass from a case of infectious disease to a childbirth without taking any precautions whatsoever. The result of such a state of things can readily be imagined.

One cannot leave the question of children's dispensaries and maternity schools without paying a tribute of admiration to the excellent work performed by the inspectress of the

Public Health Department in connexion with these institutions. Taking this hospital section as a whole, it may be said that, while a great deal has been accomplished, it yet furnishes a good many of the causes which help to make the health problem so pressing and so difficult to solve. There are errors of omission, there are errors of commission, and at a later date we will consider how these may perhaps be rectified or at least in some measure minimised.

### III. Section of Ophthalmic Hospitals.

Turning to Section III. we find we are again concerned with hospitals, but with hospitals of a special class. We are at once in touch with a great and beneficent charity, excellently organised, admirably conducted, which has brought relief and cure to thousands, which many have good reason to bless, and which no Britisher can study without a feeling of pride and satisfaction. If the British occupation of Egypt had resulted in nothing beyond the establishment of the ophthalmic hospital system, it might still have been claimed for it that it had conferred a great boon upon the inhabitants.

*Prevalence of trachoma.*—This campaign, however, owed its inception to private philanthropy, for at first the expenses were defrayed out of a fund provided by Sir Ernest Cassel. This was in 1903, and prior to that date practically nothing was done for eye diseases in Egypt, although no less than 4½ per cent. of the total population was blind in one or both eyes. At first there was only one travelling hospital, but the zeal, energy, and skill of the director soon led to a much larger organisation, and at the present time there are 13 permanent eye hospitals and five travelling hospitals, with a staff of 29 doctors, carrying on a most beneficent prophylactic and curative work. These hospitals also serve as training centres in ophthalmic surgery, and many medical men have passed through the post-graduate courses held in them. A visit either to a permanent or temporary ophthalmic hospital is, as I can testify, full of interest. Women and children form the greater number of the patients who suffer from trachoma, trichiasis, corneal opacities, cataracts, and indeed every form of eye affection. Let us hope that those who have still their sight or whose vision—praise be to Allah!—is restored benefit from what they see of the cleanliness, smartness, and order of these model hospitals. The people flock to them, 81,000 patients being now treated in them annually, and, best sign of all, for imitation is the sincerest flattery, various provincial councils have established ophthalmic hospitals of their own, while the medical service of the Ministry of Waqfs, a Ministry which controls large funds from Moslem sources earmarked for charitable purposes, possesses a special eye hospital at Kalaoun in Cairo. As the sectional director reports, "the provision of means of ophthalmic relief is one of the few things besides education in which the Egyptian has taken a keen interest, and it is frequently stated in native circles that the provision of ophthalmic hospitals reflects more credit on an individual or group of individuals than the building of a mosque." All this is very gratifying, but there is still need of expansion. The provinces of Qena, Assuan, and Qaliubia have been left out in the cold, and there the poorer classes suffer, and have, so far, little chance of remedy. But the section is not only concerned with hospital work. Its activities have extended to the Government primary schools, for it has been recognised how important it is to obtain trachoma cases at an early stage and cure them before irremediable damage has been done. Actually 90 per cent. of the pupils show signs of the disease either in an active or passive form. The pressing question now is to apply the same methods of inspection and treatment to the kuttabs, or infant schools. It will cost £E.40,000 per annum to do so, but it is well worth the money, which should be obtainable from local sources.

*Campaign against ankylostomiasis.*—Yet another duty devolved on the ophthalmic section when at the instance of the late Lord Kitchener it undertook a campaign against ankylostomiasis not very long before the outbreak of war. As the Egyptian Government did contribute something towards the expenses of this campaign the Britisher may perhaps view it with feelings less mingled than those with which he regards other campaigns against the hookworm in various British Colonies and Protectorates, or, indeed, that waged under the auspices of the Church Missionary Society in Egypt itself. In this case, as elsewhere

throughout the world, Great Britain has been in large measure content to allow its American cousins, or as one now might almost say, brethren—brothers in arms at least—to assume its responsibilities and to do work which, rightly speaking, it should have done. Whatever may be our views as regards the utility of the methods employed (and I may say that not a few believe that it would be better to concentrate attention on ankylostome breeding places and not on the victims of the disease)—whatever our views, all honour must be ascribed to the Rockefeller Institute for what it has achieved, not only in the States and in countries under the Stars and Stripes, but in British Colonies and Protectorates. We owe it a debt of gratitude, but surely it is strange that the British Empire, which is not lacking in millionaires and which stands *in loco parentis* to hundreds of thousands of sufferers from the hook-worm, should complacently accept this gift of money and of workers from America, and do little more than afford facilities for treatment and research. I confess it has always seemed to me an attitude unworthy of a world-wide Empire which, thanks to Sir Patrick Manson and the presence of our far-flung possessions, was the pioneer nation in the study and treatment of tropical diseases. Let us hope that once we all settle down this reproach will be removed, and that we will take up such part of the white man's medical burden as rightly falls to our share.

#### IV. Section of Epidemic Diseases.

We have already paid a well-merited tribute to the efficiency of Section IV., which controls epidemic disease, and from the list you will see the various branches of the work with which it is concerned. Outbreaks of typhus and relapsing fever are seasonal in Egypt, and during the epidemic season you will find scattered about the country the temporary hospitals or cordons run by this section. They are simple structures, but are well designed to cope with emergencies and they combine efficiency with economy. There can be no higher praise. Similar hospitals deal with plague patients, while this section has a special epidemic staff in the provinces, where it also possesses disinfectors and rat-catchers.

Vaccination, a most important duty, falls to its share, and it is ever bustling and busy, as indeed it must be, for the motto when dealing with epidemic disease, especially in a country like Egypt, must ever be, "Strike early, strike quickly, and strike hard."

You will notice that pilgrims and passenger control figure in the list, and let me say at once that this has nothing to do with international quarantine. The control is exercised over all passengers arriving from cholera-infected countries once they are safely ashore. It supplements the work of the International Quarantine Board, of which it is convenient to speak here, though very briefly. It will be remembered in our first lecture that we began by considering the part which Egypt plays as a filter for communicable disease. This filtering action has in the past been conducted, and very well conducted, under the ægis of a somewhat heterogeneous body, over which presided for many years a man of brilliant parts, with the pentecostal gift, with many of the qualities of genius and an abundance of tact and discretion, a man whom, alas! the sea which he loved so well and with which he had so many dealings claimed for its victim, as it has claimed so many in the late war. I refer to Sir Armand Ruffer, under whose guidance the Board guarded Egypt faithfully and well. His monument is El Tor, the great quarantine station which he established in the Sinai Peninsula, and where he encouraged and promoted research work upon cholera, plague, and dysentery. In addition, the Board carried out much port work at Abu Saad near Jeddah, at Suez, at Port Said, and at Alexandria. It may be said that it did not control the Hedjaz railway, which had its land lazaret at Tebuk, nor did it look after Indian pilgrims, for whom the Indian Government provided a quarantine station at Camaran, a station wiped out by the Turks.

As it acted under the terms of the Paris Convention the Board could only apply quarantine against cholera-infected ports and not countries, and yet a port might be free and part of the country to which it belonged infected. Hence the Epidemic Section could furnish most useful help by inspecting and registering passengers on arrival from cholera-infected countries. Pilgrims also returning after quarantine

at El Tor were dealt with, and medical officers of the places to which they were returning were notified so that surveillance could be instituted, and, if necessary, specimens taken for bacteriological examination.

Mulids are fairs, and great nuisances as centres of infection. The other items do not call for special notice here. We will meet with the barbers in due course, while the Frontier District Control has to do with new conditions arising out of the war.

On the whole it may be said that this section rather solves than creates problems. It saves lives and it saves money, many lives and much money, and few English folk in Egypt outside the Public Health Department know much about it or its work. The village Omdehs and Sheikhs, however, know all about it, and, I believe, usually appreciate these mushroom hospitals of wood and matting.

#### OTHER SERVICES: PUBLIC HEALTH LABORATORIES.

So much for the four sections. Of the other services which you observe also form part of the central administration, I propose to consider only two, the Public Health Laboratories and the Inspectorate of Pharmacies.

The laboratories, which are under a most capable director, and which have rendered great service to the cause of health in Egypt, were started in 1896 by Sir John Rogers, and from modest beginnings have attained respectable proportions. There is, however, a very pressing need for an extension in the accommodation provided, especially as regards the chemical and bacteriological laboratories. At present there is no protozoologist, and yet the pathogenic protozoa play no unimportant part in Egyptian pathology, as witness *Entamoeba histolytica* and *Leishmania tropica*, the causes respectively of amoebic dysentery and oriental sore.

You will note that small-pox vaccine is manufactured at an institute attached to the laboratories, while there is also an Antirabic Institute—a very necessary establishment in a land where rabies is common and where the bites received from rabid dogs, wolves, and jackals are often fatal and severe. It is a very interesting place, this institute, with its crowd of patients, mostly blue- or black-garbed fellahs or ragged slum-dwellers, but with a sprinkling of all classes of the community. The dexterity with which the inoculations are given is remarkable, and many patients must yearly be saved from the horrors of hydrophobia.

The Vaccine Institute, though small and somewhat archaic in the matter of special apparatus, is well run and fulfils a very useful function. Buffalo calves furnish the supply of lymph which, from the results obtained, evidently possesses good immunising powers. In a country like Egypt, where small-pox is rife, such an institution is essential and it should be kept up to date in every particular.

Allowing for the value of the vaccine lymph produced, deducting the fees paid for treatment at the Antirabic Institute and those received for analyses, the annual upkeep of these excellent laboratories only amounts to about £E.5000. As their director has modestly stated:—

"For this sum the Government obtains a reasonably efficient bacteriological and chemical service, including the following regular services: 1. Bacteriological diagnosis for the whole of Egypt except Alexandria. 2. The diagnosis work of the city of Cairo. 3. A regular bacteriological and chemical control of the Cairo water-supplies. 4. The analytical work of the Inspectorate of Pharmacies. 5. All bacteriological and chemical examinations required for the General Sanitation, Epidemic, and Hospital Sections of the Department and for the Cairo Inspectorate, the work for the latter including a regular milk control and a bacteriological control of the Cairo aerated water and ice supplies."

Here indeed is a worthy record of work, and, in addition, research is conducted as opportunity offers, while the director acts as scientific adviser to the department which he serves.

The Water-Control Service, which comes under the Laboratories, is yet in its infancy, but it is an important development, for if water plays a paramount part in the well-being of Egypt, it is one of the chief sources of trouble from a hygienic and economic standpoint, and water-supplies everywhere require to be regularly inspected and adequately controlled. Moreover, a careful study is required of the manifold problems connected with drinking-water in Egypt.

*Inspectorate of Pharmacies.*

It is, perhaps, a little surprising to see an inspectorate of pharmacies figuring as an important branch of public health administration, but pharmacies play quite a peculiar part in Egyptian life, and many of them require close supervision. Some day someone may write a romance of Egypt with pharmacies well in the foreground. It is doubtful if permission could be obtained for the publication of such a work, but if it ever saw the light of day what tales would be forthcoming about the smuggling of forbidden drugs, about opium and cocaine, about the sale of aphrodisiacs, abortifacients, and patent medicines, about the trade in spices and perfumes, about poisons, and especially those grown in Egypt, such as hyoscyamus and datura. All kinds of abuses exist, for pharmacists, ignorant of medicine, usurp the duties of the medical man, and drugs are adulterated or tampered with to the detriment of purchasers. The Inspector of Pharmacies has his own problems to face, and he will be greatly helped when the Capitulations are abolished, when new legislation is introduced, when private laboratories are better controlled, when facilities for the inspection of pharmacies are increased, and when an official pharmacopœia is duly recognised in Egypt.

*SEVERANCE OF PROVINCIAL ORGANISATION.*

The graph (No. 1) would seem to indicate that our proper course would now be to discuss the provincial organisation, but before doing so it is necessary to point out that of late years the Public Health Department has suffered some loss in efficiency through a tendency towards the severance of certain of its services from the Central Administration. In addition, some government medical services in Egypt have never been within the fold. As examples of these statements I may cite the medical services of the railways, police, prisons, and coastguards, and what is known as the Central Medical Commission, which is concerned with the medical examination of candidates for Government posts.

As the special Public Health Commission reported last July:—

"A department like that of Public Health may be likened to one of the Great Powers with many possessions. So long as the central grip is firm and the responsibilities fully recognised the component parts will remain united, but the first sign of decadence and weakness is often a tendency towards disruption."

The proposals submitted for checking this tendency and remedying the existence of this state of affairs will be dealt with in due course. Meanwhile, it seems advisable to say a few words about the municipalities and local commissions which, with the provincial councils to which passing reference has been made and which are like county councils in England, form the hope of local self-government and town development in Egypt. On this account it is upon them also that the responsibility of grappling with many sanitary problems will assuredly fall.

*Functions of Municipalities.*

Time will not permit an historical survey of the foundation and progress of the municipalities and local commissions; they come under the Ministry of the Interior, but are quite distinct and separate from the Public Health Department. Yet they are largely concerned with sanitary engineering and with public works which have a distinct bearing on the health of the people—such works, for instance, as the care and maintenance of roads and cemeteries, water-supply, scavenging, and the superintendence of slaughter-houses. They are also concerned with lighting, and let it always be remembered that a dark town is a dirty town in more ways than one. The municipalities exercise their functions in some of the larger provincial towns, the local commissions in 35 of the smaller towns of Egypt. They are in some ways analogous to municipal councils and town councils in this country, and are administered in an able manner by a British director, who happens, fortunately, to be a medical man. Already they have accomplished much good work, some of which we shall look at in a moment, and, considering the ever-increasing burden of expense in public health matters, a load which no Central Treasury can possibly shoulder, it is clear that the municipalities and local commissions must remain apart and form the nucleus of a future scheme whereby the municipalities will manage their own health affairs under the guidance and advice of the Ministry of Health.

**OBSERVATIONS ON AORTIC DISEASE IN SOLDIERS.**

BY THOMAS F. COTTON, M.D. MCGILL.

(A Report to the Medical Research Committee.)

DURING the past winter an unusually large number of soldiers presenting signs of aortic disease were admitted to the Sobraon Military Hospital, Colchester. The majority of these were young men who had been passed fit for general service, and all but a few had seen active service abroad. The opportunity seemed a favourable one for making a careful study of the symptoms associated with this form of cardiac affection, and their significance; and of the signs used to recognise this valvular defect, and their value in estimating the stage of development of the disease.

*Analysis of 50 Case Histories.*

In dealing with the symptoms I have analysed the case histories of 50 soldiers with signs of aortic insufficiency. All of them were submitted to a complete physical examination, and the description of the signs is based on this examination. The exercise tolerance was determined in these 50, and 17 others, by observing their reaction to a simple exercise test; in 8, graded exercises as employed in the treatment and sorting of the D.A.H. cases, were used as a test of physical fitness. The histories which these men have given throw considerable light upon the causation of the symptoms which they complain of. If they can be interpreted as symptoms arising not from loss of cardiac reserve, and can be explained by some other cause than the valvular defect, then the difficult task of forecasting the future welfare of the patient suffering from this heart malady becomes an easier one.

I am not concerned here with the causation of the symptoms in patients with advanced aortic disease. These observations refer to a group of soldiers with an average age of 31 years; men who have been in the Army for an average period of 2 years and 7 months, including 1 year and 7 months' military service overseas. These men presented no signs of venous engorgement, and the pain which they complained of was not anginal in character or distribution.

In 30 the average duration of symptoms was 1 year and 7 months; in 12 the symptoms extended over a longer period, and were present before enlistment. Half of these had been in the firing line, 4 had not been abroad, and with the remainder only light duty at the base had been performed. Before enlistment the occupation had been a heavy one in 36 per cent., moderately heavy in 41 per cent.; and light work only in 23 per cent.; 62 per cent. played games such as football, cricket, and tennis before enlistment. Only 12, or 27 per cent., gave a history of rheumatic fever, a very low incidence. One gave a history of syphilis. In 35 the complement-fixation test was done, and of these the reaction was positive in 8, or 23 per cent.; all of these 8 were over the age of 40 but one, who was 22.

*Determination of Exercise Tolerance.*

In 27 of those with slight incompetence and 16 with free regurgitation the exercise tolerance was determined by observing the response after a brisk walk up and down 20 steps twice. Distress after the effort accompanied by a rapid pulse-rate with a slow return to the pre-exercise rate were considered signs of poor exercise tolerance. If there were no complaints, and no obvious signs of distress, with a moderate increase of pulse-rate, and a quick return to the pre-exercise rate—i.e., less than two minutes—the reaction was looked upon as good. In 24, 12 with slight incompetence and 12 with free regurgitation, the symptoms alone, after the same exercise test, were used in estimating the physical fitness; the pulse-rates were recorded in these with a Mackenzie polygraph for five minutes before the exercise with the patient sitting, and the average was taken as the pre-exercise rate immediately after the effort, and at the end of two minutes. In those of the first group, where the tolerance was determined by the symptoms and the pulse-rate, 14 with slight incompetence of the aortic valve had good exercise tolerance, and the average pulse-rates were 77 before the test, 123 immediately after, and 73 at the end of two minutes; 13 had poor exercise tolerance, and the average pulse-rates were 93, 157, 109; 10 with free regurgitation had good exercise tolerance, and the pulse-rates 72, 123, 81; 6 had poor tolerance, and the rates were 84, 166, 113. Of the second group, with the tolerance determined by the symptoms alone, 3 with slight incompetence had good exercise tolerance, with average pulse-rates of 82, 132, 85; 4 had poor tolerance, and the rates were

97, 139, 105; 5 with free regurgitation had good exercise tolerance, with average pulse-rates of 89, 137, 94; 7 had poor tolerance, and the rates were 99, 153, 120. If these two groups are combined, it will be seen that of the 39 early cases the reaction is good in 22, and the average pulse-rates are 79, 130, 81; the reaction is poor in 17, and the pulse-rates are 94, 153, 108; 28 had free regurgitation, with good tolerance in 15, and pulse-rates of 77, 127, 86; 13 poor tolerance, and pulse-rates of 92, 159, 116.

#### Diagrammatic Representation of Results.

In the diagrams I have plotted these average pulse-rates. In *Diagram I.* the broken line and the line with the circles represent the average pulse-rates of the 27 early cases, with the tolerance determined by the symptoms and the pulse-rate; the unbroken line and the line with the black dots represent the pulse-rates of the 16 with free regurgitation and the tolerance determined in the same way. The figures at the side are the pulse-rates. Where the tolerance is good the summits of the curves are at approximately the same height, and at a much lower level than those with poor tolerance; the actual increase in rate after effort is the same.

tolerance is good in 56 per cent. of the former and 54 per cent. of the latter. When a comparison is made of the exercise tolerance in all with aortic disease 55 per cent. are found to have good tolerance and 45 per cent. poor tolerance. When the tolerance of the 67 with aortic disease is compared with that of 25 unselected D.A.H. cases, 55 per cent. of those with valvular disease are found to have good tolerance, as against 56 per cent. of those with D.A.H.

The points which I desire to make, and which I think these observations on exercise tolerance clearly show, are these: aortic disease is compatible with good exercise tolerance; when there is an equal degree of distress after effort the increase in pulse-rate is the same in patients with slight aortic incompetence, in aortic disease with free regurgitation where there is no venous congestion, and in D.A.H. cases in whom there are no signs of structural disease.

#### Three Types of Aortic Disease.

By the symptoms alone aortic disease may be divided into three types: (1) aortic disease without symptoms; (2) aortic

I.

III.

IV.

Composite diagram showing average pulse-rates before exercise, immediately after, and at the end of two minutes. The broken line (— — —) indicates slight regurgitation and good tolerance; the line with circles (—○—) indicates slight regurgitation and poor tolerance; the continuous line (—) indicates free regurgitation and good tolerance; the line with black dots (—●—) indicates free regurgitation and poor tolerance. I. Tolerance determined by symptoms and pulse-rate. II. Tolerance determined by symptoms alone. III. Curves I. and II. combined. IV. Aortic disease, including those with slight regurgitation and free regurgitation, with tolerance determined as in I. and II. and D.A.H. (the broken line and the line with circles indicate the D.A.H. cases; the continuous line and the line with black dots indicate those with aortic disease).

When the tolerance is poor the increase in rate is considerably greater than in those with good tolerance, and the rate is at a higher level in those with free regurgitation than in the early cases.

In *Diagram II.* the pulse-rates are those of the 24 with the tolerance determined by the symptoms alone. The summits of the curves are slightly higher than in *Diagram I.* when the tolerance is good, and at a lower level when the tolerance is poor. The high points are not so far apart, and the peaks are lower in those with poor tolerance than in *Diagram I.*

In *Diagram III.* I have combined *Diagrams I.* and *II.* In those with good tolerance the peaks are low and the rise is the same. In those with poor tolerance the peaks are considerably higher, with a greater rise after effort in those with free regurgitation, and a fall after two minutes which does not reach the pre-exercise rate.

In *Diagram IV.* I have plotted the pulse-rates before and after exercise of 67 patients with aortic incompetence—37 with slight regurgitation and 30 with free regurgitation; and also the pulse-rates after the same exercise of 25 unselected D.A.H. cases, with the exercise tolerance determined by the symptoms alone, and the pulse-rates recorded with a Mackenzie polygraph. In those with good tolerance the pulse-rate rises to approximately the same height, both in the D.A.H. case and in the patient with aortic disease, and at a much lower level than in those with poor tolerance. When the tolerance is poor the level is slightly higher in those with D.A.H., and the fall about the same after two minutes.

In those with slight incompetence of the aortic valve, as compared with those with free regurgitation, the exercise

disease with a group of symptoms which we term "the effort syndrome"; (3) aortic disease with venous engorgement or angina pectoris.

With aortic disease of the *first type* there are no symptoms, and the condition is recognised by the signs alone. Fully developed incompetence of the aortic valves is compatible with good exercise tolerance; the severest form of exercise can be performed without greater distress than that observed in a healthy untrained subject. The extra load put upon the heart by the reflux of blood through the defective valve is cared for by the large reserve power which a healthy or slightly damaged myocardium possesses. Not until the cardiac muscle has been sufficiently impaired—for example, through coronary or myocardial disease—does the heart fail to bear the extra work put upon it, and with the exhaustion of its reserve give rise to the symptoms of heart failure. The uncomplicated valvular defect, the simple crumpling of the aortic cusps, is not in itself of great consequence. The reason that in so many aortic disease leads to heart failure is that the coronary arteries, or the myocardium, or both, have been damaged by the same agent that has caused the valve defect.

The *second type* presents the effort syndrome group of symptoms. Breathlessness on exertion is always present; this respiratory distress is provoked by an effort which, in a healthy person, would not be complained of. It is absent at rest save in rare instances. Occasionally it is noticed at night in bed, and is described as a choking sensation, a feeling of suffocation; it is sudden in onset and of short duration. This is not to be confused with the nocturnal breathlessness due to deficient aeration of the lungs, nor

the paroxysmal dyspnoea of relative acidosis in cardio-renal disease. It is as frequently met with in the effort syndrome case where there are no signs of structural disease. Palpitation is a common complaint. When provoked by exercise it is felt after the effort; it is associated with an overacting heart and persists as long as the excessive heart-rate is maintained. Emotional stimuli—excitement, fear, pain, joy, &c.—give rise to the same symptom. Palpitation is complained of by many in bed at night; often, but not always, it is noticed when the patient lies on the left side, and disappears with a change of position. In some way it is related to the breathlessness at night for the two symptoms often occur together. Giddiness is present in many. Sometimes it is felt after exercise, as often with change of position, as in bending or suddenly assuming the erect posture. In a few there is experienced in bed at night a peculiar sinking feeling, a sensation of falling through the bed or floor, or actual loss of sense of position, quite like the giddiness produced by effort. Observations upon the blood pressure and pulse-rate have been made to explain this condition. This symptom is caused in some way by an altered cerebral circulation; the mechanism by which it is produced has not been determined. Pain is an important feature of the disease. It may occur after effort, but it is often felt at rest; occasionally it is complained of at night. Some describe it as a stitch in the left chest, or a sharp cutting pain in the region of the left costal border, over the heart, or in the back, while others have a dull boring pain, or soreness over the precordium. Exhaustion after effort is much greater than that experienced by a healthy individual, and lassitude in the morning is a common complaint. Headaches are frequent; they occur in the morning, and are usually frontal in situation. Sweating, flushing, mental irritability or depression, are less constant symptoms. The hands are cold, clammy, cyanosed, and often tremulous, and drops of sweat run down from the axillæ. These are the symptoms observed in soldiers with aortic disease before venous engorgement has made its appearance. Briefly, the symptoms in D.A.H. so-called and in the aortic cases are identical, indistinguishable the one from the other. How are they produced in the aortic cases? If the symptoms in aortic disease of this type arise from cardiac weakness, and are caused by cardiac inefficiency; if they are to be explained by the inability of the heart to carry on its work from myocardial weakness, and the added load put upon it by the reflux of blood from a defect in the aortic valve; if that is the true explanation it is difficult to account for the symptoms in the D.A.H. case where we find no signs of structural heart disease. It might be thought that the two groups differ in their onset of symptoms. Now the symptoms in aortic disease arise from a variety of causes. They appear in a large number after an acute infection—after rheumatic fever, pneumonia, bronchitis, trench fever, malaria, and dysentery. In some gas poisoning is the agent, in others shell shock; some date their symptoms from a severe effort; in others the symptoms are gradual in their onset and cannot be associated with any particular cause. But with the D.A.H. case the onset of symptoms are as I have described for aortic disease; acute infections, gassing, shell shock, effort, and conditions of active service or civil life, all have the same ætiological significance; this, we all agree, has been established. It seems fair, then, to ascribe the symptoms in the group of aortic cases to the same causes, when there is an equally clear history. Do not misunderstand me. I do not speak of the causes of aortic disease; I am dealing now only with the ascribed causes of the symptoms. In both the provocative agents are the same, and in both the symptoms are identical. Here let me add one word about the ætiology of the two conditions; the incidence of rheumatic fever is much higher in aortic disease in those under the age of 40 than in D.A.H., and the incidence of syphilis is higher in disease of the aorta over the age of 40. I have referred at some length to the similarity of the symptoms in the two groups. I do so because I wish to give you the view which we who have worked at Colchester hold; that the symptoms of early aortic disease in soldiers are not produced by the extra work put upon the heart by the valvular defect, but are due to the same causes as are the symptoms in D.A.H. In other words, that disease of the aortic valve in itself gives rise to no symptoms.

Now of aortic disease of the *third type*, where there is venous engorgement or angina pectoris, I shall be very brief. They are not the symptoms of aortic regurgitation but those of heart failure. With venous engorgement we have the symptoms of venous stasis in the pulmonary circulation on the one hand—cyanosis, orthopnoea, and pulmonary congestion; and on the other, the symptoms arising from the failure of the heart to maintain the general circulation—œdema of the extremities, general anasarca with disturbance of the renal and other abdominal visceral functions, cerebral manifestations, and the final moribund state of the human organism. Of the characteristic picture of angina pectoris in advanced aortic disease, I shall only say that it is rarely seen in the presence of venous engorgement, with enlargement of the liver, and with the onset of dropsy the pain disappears.

#### *The Value of Physical Signs.*

I have dealt only with symptoms and their significance in aortic disease. The signs are equally important, for they are the guide to diagnosis, and assist us in prognosing the future life of the patient. By the signs alone are we able to diagnose incompetence of the aortic valve. They may be classified as signs of slight insufficiency of the aortic valve, and signs of aortic incompetence with free regurgitation. When the disease has sufficiently advanced, and heart failure has set in, then new signs are added. The most constant sign by which we can recognise early aortic disease is a diastolic murmur. This murmur is best heard at the left border of the sternum at the level of the third rib or third intercostal space. When heard over the aortic cartilage it is more distant; the diagnosis may have to be made when no murmur is heard over this area. During this stage of the disease the heart may be slightly enlarged; frequently, however, there is no increase in the area of relative cardiac dullness. The pulse is not collapsing; there is no conspicuous pulsation of the carotids or the brachial arteries; and the blood pressure range is within normal limits. With the development of free regurgitation chief reliance should be placed upon the character of the pulse: the collapsing, water-hammer, or corrigan pulse. There is throbbing of the carotids and brachials, capillary pulsation is always present, the pistol shot phenomenon is commonly present, the systolic blood pressure is higher and the diastolic is relatively low, and there is material enlargement of the heart. When venous engorgement occurs the signs of venous stasis are added. With the progress of the disease the heart increases in size, its area of relative cardiac dullness may extend to the anterior, mid-axillary line, or further. It is generally held that the dilatation and hypertrophy is mainly that of the left ventricle, and is produced by the extra work put upon this chamber by the reflux of blood through the incompetent aortic valve. Now the signs by which we recognise cardiac enlargement are an uncertain indication of the preponderating hypertrophy in one or other ventricle. Increase in cardiac dullness to the left does not necessarily mean left ventricular hypertrophy, and epigastric pulsation is a very unreliable sign of hypertrophy of the right ventricle. The electro-cardiograph offers means of accurately determining the comparative degree of hypertrophy in one or the other chamber. One frequently observes in electro-cardiographing patients with aortic disease that hypertrophy is equally borne by the two ventricles, so that the normal relationship of the two is maintained, and in some the predominating hypertrophy is in the right ventricle. By weighing separately the ventricles of patients whom Lewis and I had observed during life with signs of aortic disease we were able to confirm the electro-cardiographic records.<sup>1</sup> Such observations do not support the hypothesis that hypertrophy in aortic disease is produced solely by the regurgitation of blood through the defective aortic valve. Some other theory must be sought to explain the causation of hypertrophy in aortic disease. Such observations favour the view that myocardial disease is the chief factor in the production of cardiac hypertrophy, and in the causation of the symptoms of heart failure.

#### *Prognosis in Aortic Disease.*

A difficult task awaits those who attempt to forecast the duration of life in aortic disease during the early stages of its

<sup>1</sup> Cotton: Observations on Hypertrophy, Heart, vi., 217.

development. Prognosis becomes easier as the disease progresses and signs of cardiac failure make their appearance. There are certain symptoms, and of these pain is one of the most important, which guide us in estimating the number of years remaining before the final stage of total disability has been reached. Dyspnoea at rest with cyanosis and pulmonary congestion, and pain that is anginal in character and distribution and felt after slight effort, are symptoms that we all recognise as indicating a grave heart affection. The disability here is a total one, and our chief concern is the relief of distress of the patient. The ultimate prognosis is easily made; the immediate one depends upon the manner in which the patient responds to treatment. A large heart means myocardial mischief. By its size one may be helped in estimating the amount of damage which the myocardium has suffered. The final breakdown is likely to occur earlier where there is great increase in the heart's size than in those without much cardiac enlargement. With no signs of heart failure, and only a moderate extension of the left border beyond the nipple line, the outlook is more favourable. The auscultatory signs are not of much help, if any, in prognosing aortic disease in its early stages. We recognise free regurgitation of the aortic valve by the character of the pulse; the quality of the murmur tells us little. It is probable that the damage to the valve is greater where there is free regurgitation, as it is certain that more work is put upon the heart. It may be that the myocardium and the coronary arteries have been injured to the same degree. With the heart not much enlarged the prognosis is less favourable when the pulse is collapsing. It is difficult to prognose with any certainty when the heart is not enlarged and there are no signs of failure. Some have no symptoms with good tolerance; others have symptoms as I have described them, with the physical capacity so reduced that only the slightest effort can be performed without distress. If we are to determine the course of the disease in these two groups then we must rely upon the symptoms alone, for the signs may be identical. The immediate prognosis—i.e., the present disability—is easily determined by submitting the patient to a simple exercise test. Other factors must be considered in arriving at the ultimate prognosis, and of these the most important is the cause of the symptoms. If symptoms in one arise primarily from myocardial disease, and in another can be ascribed to other causes not primarily cardiac in origin, then we have obtained information of great prognostic value. In the absence of a known cause such as a focal or general infection—chronic appendicitis, dysentery, or pulmonary tuberculosis—it seems to me, with our present knowledge, impossible in early aortic disease to distinguish between symptoms primarily cardiac and symptoms due to other causes. A test of our knowledge of prognosis in early aortic disease will be one based on the after-histories obtained from a large number over a long period. It may then be possible to state definitely that certain symptoms arise primarily from myocardial disease, and indicate the early onset of heart failure; and other symptoms arise from other causes and are of less consequence in prognosing the course of the disease.

#### RED CROSS AUXILIARY HOSPITALS: ANNUAL REPORT.

—The report, which deals primarily with the accounts of the Red Cross War Hospitals at home for the year ended Dec. 31st, 1918, contains also a summary of their operations during the whole period of the war. This summary shows that, excluding private hospitals—i.e., those not in receipt of capitation grants from the War Office—1,260,523 patients were admitted to the auxiliary hospitals, and were treated at an average cost of 3s. 8-78d. per patient per day for maintenance and 0-83d. for administration, a total average cost per day throughout the war of 3s. 9-61d. Of the total expenditure, £7,760,727 was met by Army and Ministry of Pensions allowances, leaving over £2,500,000 to be found by voluntary public giving. The six leading counties in the matter of patients admitted were: Kent, 114,316; Lancashire (East), 83,619; Hampshire, 63,113; Surrey, 60,324; Cheshire, 58,117; Sussex, 49,344. The soundness of the policy, from a financial standpoint, of running large hospitals is demonstrated by the fact that whereas in hospitals with 50 beds or more the average daily cost of a patient was 3s. 11-85d., in those with 25 beds or less it was 4s. 3-41d. The report has been prepared by Mr. Basil E. Mayhew, F.C.A., secretary of the Joint Finance Committee of the Red Cross, and may be obtained from Room 70, 83, Pall Mall, London, S.W. 1, for 3s.

## THE INCREASE OF ALKALINITY OF THE BLOOD IN SHOCK.

By BENJAMIN MOORE, D.Sc., F.R.S.

THE report of the Arris and Gale lecture on the Initiation of Wound Shock and its Relation to Surgical Shock, by Dr. E. M. Cowall, D.S.O., in THE LANCET of July 26th, is of high scientific value, but in addition one cannot read it without admiring the calm courage with which these observations were made in the firing line and en route to the casualty clearing stations.

#### Results of Recent Physiological Work.

It is in no criticising spirit therefore, but because this report will be widely read by surgeons and clinicians who have to undertake the treatment of cases of shock, that I venture to draw attention to quite recent physiological work which demonstrates that there is no enhanced acidity of the blood in shock such as would warrant the use of the term "acidosis," but rather a greatly increased alkalinity which by damage to heart and nerve centres leads to that secondary shock which produces the fatal event. In this aspect of the subject Dr. Cowall is quoting the observations of others, and quotes them quite in an orthodox way, but recent work shows that they are entirely erroneous and misleading, and have warped the treatment of shock into wrong channels.

It is quite true that what has been called the "alkaline reserve" of the blood is reduced in shock often enormously, that the titration value of the alkali of the blood to acids by any of the methods, such as those of Galleotti, Wright, Moore and Wilson, van Slyke, &c., is decreased, so that the condition is described as "acidosis" or "acidemia." But this same blood is much more alkaline than the normal, and the animal is shocked and dying because its blood and tissue cells are loaded up with alkali.

It is entirely a wrong treatment to administer alkalies. What the organism requires is oxygen, carbon dioxide, and warmth, until oxidation in the tissues begins to approach its normal level. The organism has breathed off in excess its balancing carbonic acid in its attempts to get enough oxygen; it has thereby alkalinised all its cells, and this alkalinity, by its action on the state of aggregation of the molecules of the bioplasm, has disturbed the functions of heart and nerve centres. It will be one of the most remarkable records in medical science that for a generation scores of workers in Britain, the continent of Europe, and America went on calmly working on the assumption that pumping off carbonic acid left the blood more acid.

#### The Cause of Mountain Shock.

One of the pioneers in the subject was Angelo Mosso, professor of physiology in the University of Turin, who carried out many of his researches near the summit of Mont Rosa in the high Alps, nearly 16,000 feet above sea-level, in the Capanna Regina Margherita, provided for him by the Queen of Italy of that time. Mosso and his colleagues showed most clearly that mountain shock and sickness were caused by the denudation of carbon dioxide in the blood, due to excessive breathing to get in enough oxygen. The same factor appears in the shock of aviators at high level, and has recently given rise to investigations by Haldane, Priestley, and others, showing conclusively that alkalinity of the blood is a predominant factor. It has also been shown by Moore and Whitley that a slight increase in alkalinity of a saline perfused through an isolated heart leads to a typical shock, with output reduced to one-fifth of the normal, and stoppage in a few minutes.

#### Erroneous Conclusions.

But Mosso and Galleotti had not this knowledge, which has only dawned out in the last few months. Galleotti, at Mosso's request, attempted to estimate the alkalinity of the blood where shock was tending to appear at Mont Rosa, 16,000 feet above sea-level; he did it by titrating to phenolphthalein, and found the blood was much more acid. His titrations were correct, but his conclusion profoundly wrong. Similar conclusions have been drawn everywhere, for nearly 20 years since then, but they are all erroneous. They have led to patients being dosed with sodium bicarbonate to relieve shock, and to intravenous injections of acid in animals in the attempt to study shock. In practically every

variety of shock these reduced determinations of the alkali of the blood show that the animal is fighting a stern fight against alkalinity.

*"Acidosis" and "Alkalosis."*

What is the explanation of this paradox of *alkali diminished, alkalinity increased*? To the physical chemist there is no great difficulty in the proposition; the difficulty comes in explaining it to the biologist, surgeon, and physician. The outlook upon the chemical conditions in shock is all wrong, and this is why the invariably underlying presence of "acidosis," to which at first much attention was given, became later neglected. All cases of serious secondary shock show so-called "acidosis," but this acidosis is not "acidosis"; it is "alkalosis." So all the attempts of physiologists to mimic it have been abortive. What, then, is acidosis? As defined by the American physiologists, it must be admitted that in shock there is "acidosis" or reduction of the "alkali reserve." The definition of van Slyke and Cullen is that the serum must be obtained, and then in an atmosphere containing carbon dioxide to the extent of about 5 per cent. of an atmosphere be set in equilibrium. Next, the volume of carbon dioxide in c.cm. per 100 c.cm. of serum which can be evolved from this by addition of strong acid is determined; this gives the "alkali reserve." If the alkali reserve is reduced there is "acidosis"; if the "alkali reserve" is increased there is "alkalosis." The point of difference is that in individuals suffering from shock the blood is not in equilibrium with 5 per cent. of carbon dioxide, but with 2 or 3 per cent. of carbon dioxide. The blood of a shocked person while within the body breathes itself into a high state of alkalinity, and the above method of defining "acidosis" and "alkalosis" is not much better than defining "black" as "white."

When the pressure of free carbonic acid in the blood is decreased then alkalinity rises and kidneys and tissue cells remove alkali from circulation. It is for this reason that the circulating bicarbonate decreases, and so lowered titration figures are obtained, but the blood is more alkaline. A fall in bicarbonate reserve to one-third of normal can be caused by a small fall in pressure of carbon dioxide and accompanying increase in alkalinity.

*Primary Shock.*

When primary shock occurs from sudden heart failure, from emotional causes, hæmorrhage, pain, or some such stimulus, there is cerebral anæmia and unconsciousness. There may be recovery from this in a few minutes, as in an ordinary faint, but if the condition continues for a longer time, such as 20 to 30 minutes, it is interesting to consider the series of events. The primary factor is that there is a general cessation of metabolic activity at first and a shut-down later to about one-third of the normal rate. Now, if there be a closure down in the tissues to one-third, what must happen if the lungs go on working at their normal rate or even at one-half their normal rate? The answer is that an excess of carbon dioxide over that produced must be removed in the lungs and the blood go alkaline, and this is what occurs in secondary shock.

During the period of fainting both heart and respiration are held in abeyance, the heart perhaps more than the respiration, and there is a venous condition which favours recovery, but later there is a condition in which respiration exceeds circulation and the blood becomes more alkaline and carries shock to the nerve centres and heart.

*Excessive Respiration and Shock.*

It has been much disputed whether excessive respiration is a necessary antecedent to shock, some have described it, others failed to find it, in wounded soldiers suffering from shock. It is an instance of how long it takes for the obvious to strike us, the balance depends on the relative rate of working of the circulatory and respiratory systems. If as a result of a primary shock the circulation is only working at one-third of its usual speed, and the respiration is going on at usual rate, the amount of carbon dioxide produced will only be one-third of the normal, while elimination proceeds at normal rate. The result must be that the alkalinity of the blood increases, and any such increase leads to heart failure. It is thus seen that hyperpnœa need not necessarily be an antecedent factor to surgical shock, and that in the main the condition depends upon relative rates of circulation and respiration, although other conditions, such as toxic products from wounds and muscle injury and fatigue of nerve centres, undoubtedly play a part.

## THE HOT SEASON IN MESOPOTAMIA.<sup>1</sup>

By F. E. FREMANTLE, F.R.C.P. LOND.,

LIEUTENANT-COLONEL, R.A.M.C. (T.), D.A.D.M.S. (SAN.), MESOPOTAMIA EXPEDITIONARY FORCE.

THERE is evidently much uncertainty at home as regards the climatic conditions of Mesopotamia. An account, therefore, of the hot season of 1917 at Amara on the Tigris and of the cases diagnosed as suffering from "effects of heat" may be of interest. The military population during the period under review may be taken as 25,000, one-fourth being British, and one-fifth being hospital patients, mostly from other areas.

There were seven general hospitals, three British with 2000 beds, four "Indian" with 3000 beds, and an isolation hospital with 200 beds, besides British and Indian convalescent depôts for 2000 men.

*Climatic Data.*

As a preface the following facts are given as to the climatic records at the same station in June, September, and December, 1917, and in March, 1918.

	June.	Sept.	Dec.	March.
Temperature (dry bulb).				
Max. average ... ..	103°	105°	62°	70°
Highest ... ..	110°	117°	76°	80°
Min. average ... ..	78°	71°	41°	52°
Lowest ... ..	73°	60°	26°	44°
Wet bulb at 4 P.M.				
Average ... ..	72°	73°	52°	57°
Highest ... ..	79°	82°	59°	64°
Lowest ... ..	67°	67°	44°	52°
Humidity at 4 P.M.				
Average ... ..	—	—	54	50
Highest ... ..	—	—	99	87
Lowest ... ..	—	—	22	26
Daily wind movement.				
Average (miles) ... ..	442	188	135	171
Highest " ... ..	730	480	389	406
Rainfall in inches.				
Total ... ..	Nil.	Nil.	1.43	1.65
No. of rainy days ... ..	"	"	7	8
Greatest in one day ... ..	"	"	0.71	0.90

In fact, the first quarter of the year is the only rainy quarter and is about as rainy as in England; the third quarter is the unpleasantly hot season; the second is cooking up for it; the fourth, like the first—with the exception of only a few rainy days—is delicious.

The freshness of the spring depends partly on the prevailing northerly winds, blowing down from the mountains of Kurdistan or occasionally from the neighbouring Pushti-Kuh to the north-east; partly on the floods, which must, by evaporation, help to keep down the temperature in early summer.

The floods depend more on the height of the Tigris than on the local rainfall; and the height of the Tigris depends firstly on rainfall in its upper reaches, and then on the melting of the snows in the mountains.

The river is at its lowest here, from 22 to 23 feet above mean sea-level at Fao, from September to November; and after a temporary rise of a foot in December, rises suddenly in January to 27 or 28 feet, and falls in February to 24 to 25 feet. In mid-March it again rises to its maximum of 27 to 28 feet, and, with or without a remission of a foot, remains constant till the beginning of May. It then begins its slow, steady fall from 27 to 22 feet, spread over four months.

Below the DIALA there are no tributaries to the river; but the Hai at Kut, the Chahala and Masharrah at Amara, the several canals and frequent irrigation channels serve as outlets which spread the rising waters over the face of the land, mostly to be absorbed or evaporated, while the remainder enters the Tigris again below the Narrows or, through the Euphrates, joins the Tigris at Qurnah to form the Shatt-al-Arab, running out into the Persian Gulf at Fao. The whole country to windward is therefore moist till harvest-time in April and May. It then dries and the dry heat increases pitilessly day after day.

<sup>1</sup> A paper read before the Amara Clinical Society in May, 1918, and revised in 1919.

*Relation of Temperature to Incidence of Cases.*

The figures in the temperature chart prepared for this paper were those recorded daily at the Meteorological Station at 8 A.M. each morning for the previous 24 hours and were shown for the day previous to that on which they were reported, so as to correspond in general to the day on which the effects of heat occurred.<sup>2</sup>

This station is in the open, fully exposed to the prevailing N.W. wind blowing right down the upper reach of the Tigris. The air here is noticeably cooler and probably moister than elsewhere; and the figures are probably the lowest in the place. Almost equally trustworthy figures taken in verandahs of hospitals and elsewhere often showed dry-bulb temperatures from 6°–10° higher, even up to 130°, and a trustworthy assistant surgeon at a marching post recorded 140° one day in a 160 lb. tent.

The chart showed dry-bulb maximum varying in these three months from 92° to 121°, with two intense spells, one between 110° and 121° from July 7th to 25th, the other between 108° and 121° from August 16th to Sept. 13th.

The curve showing cases of effects of heat presented two corresponding rises, but more sharply marked and of far shorter duration. In the first spell no more than three cases occurred each day until July 14th, no case occurring on the hottest day—the 10th. In the second spell over three cases a day occurred only between August 19th and Sept. 4th, 14 cases occurring on the day of greatest heat, and 18 on the following day, when the maximum temperature was 11° lower at 110°. Nor did the other two temperature curves correspond to that of the cases of effects of heat, for the minimum dry-bulb temperature reached its highest (88°) on July 17th and 20th, after the case curve had made its chief rise; and the wet bulb at 4 P.M. was highest (83° and 82°) on days when there were 1, 10, and no cases respectively, fewer even in the second instance than on the previous day, when the wet bulb read only 73° and there were 18 cases.

There was, however, a certain correspondence on several occasions between a high minimum—i.e., a hot night—and the number of cases next day; and there was a general correspondence between the heat waves at their height and the number of cases.

The number of cases in June was too rare to attract special notice; and it would appear that it took several days or weeks of heat before the susceptible individuals succumbed to it; and those remaining were more liable to be immediately affected by the second spell of extreme heat towards the end of August.

The failure of the wet bulb to give any useful indication of the danger suggests, as Professor Leonard Hill has pointed out, that the most important preventive factor is the rapidity of cooling, dependent on movement and negative humidity of air and its free play over the surface of the body under the clothes. It was to meet this suggestion that the kata-thermometer has been devised to show rapidity of cooling; and the readings on this instrument should be most carefully recorded and studied in every future hot weather.

*Effects of Heat.*

The clinical facts, as complete as possible, were taken from the hospital returns received on the special notification form<sup>3</sup> and from a special return of deaths due to effects of heat. Cases were shown under the day on which they first suffered. All cases diagnosed in hospital as "effects of heat" were included, whether otherwise diseased or not. The cases occurred between July 8th and Sept. 11th, with the addition of one case marching up with an echelon and admitted on Sept. 21st.

No. of cases recorded, 353; deaths, 49.

Second attack recorded in 4 cases, of which death occurred in 1.

Third attacks, 0.

Officers, 5; Indians, 16; Arabs and others, 0.

<sup>2</sup> A full chart of daily temperatures and cases of effects of heat, admitted to hospital, was exhibited with this paper but was lost in transmission home. It showed the dry bulb maximum and minimum and, in the absence of a wet bulb maximum thermometer, the wet bulb temperature at 4 P.M. daily throughout July, August, and September, as well as the number of cases each day.

<sup>3</sup> The notification form set out the following heads:—No., rank, and name; regiment; unit to which now attached; camp, billet, aid-post, &c.; from which case admitted; if already a patient, previous diagnosis; date and hour of attack; occupation at the time; whether constipated; malarial history—parasites; max. temp. of case; progress since admission; remarks.

*Predisposing Causes.*

(a) Disease:—Malaria: History, 64; B.W. fever, 1; smears B.T., 11; attack, 3.

Other cases actually in hospital at the time had been admitted with—

Sandfly fever ... .. 7	Amoebic dysentery ... .. 2
Anæmia and debility ... .. 7	Enteric group ... .. 2
Gastric or intestinal ... .. 6	Cardiac ... .. 2
Various and N.Y.D. ... .. 6	Bronchitis ... .. 1
Septic conditions ... .. 5	Neuroses ... .. 1

(b) Constipation: Yes, 122; no, 196.

*Time of Commencement of Attack.*

00.00–06.00	...	...	13	cases, including	4	on	16/7/17
06.00–09.00	...	...	21	"	"	4	" 23/8/17
09.00–12.00	...	...	56	"	"	{ 8	" 16/7/17
12.00–15.00	...	...	42	"	"	{ 5	" 23/8/17
15.00–18.00	...	...	92	"	"	{ 9	" 18/7/17
18.00–24.00	...	...	27	"	"	{ 7	" 22/8/17
						—	—

Total ... .. 251 cases.

05.00 = 6 A.M.; 18.00 = 6 P.M., &c.

Attack came on gradually in a large proportion of the trivial cases—probably in the great majority of them.

*Types of Cases.*

Trivial (temperature below 104°), 177.

Moderate ( " 104°–106°), 83.

Severe ( " 107° or above or grave symptoms), 78.

*Hyperpyrexia* (over 105°), out of 353 cases and 49 deaths:—

No. of cases.	Deaths.	No. of cases.	Deaths.
105°–106° ..... 18	3	109°–110° ..... 14	5
106°–107° ..... 23	2	110°–111° ..... 9	3
107°–108° ..... 26	4	111° ..... 1	—
108°–109° ..... 26	6		
		117	23

*Occupation at time of attack:—*

On duty ... .. 117	Bathing ... .. 1
Off duty ... .. 33	Not stated ... .. 94
Resting ... .. 108	

*Occupation of those attacked 15.00–18.00 (3–6 P.M.).—*Of 92 for which occupation was recorded 30 were not resting, and were thus occupied:—

Fatigues and grave-digging ... 5	Movement or waiting—
On guard or police ... .. 4	In sun on duty ... .. 3
Parade (2), orderly corporal ... 3	Duty not specified ... .. 3
Transport, driving, grooming... 3	Office duty, mess duty ... .. 2
Butchery, bakery, cook ... .. 3	R.A.M.C. duties ... .. 2
	On steamer ... .. 1
	Bazaar ... .. 1

*Aid-posts.*

Six aid-posts were established in May, some on the 5th and the rest by the end of that month, at important centres, such as bridgehead and railway station. They were staffed by 23 British privates in charge of a R.A.M.C. corporal, succeeded by a sergeant, an ex-policeman, under the direct supervision of the officer commanding a sanitary section.

These aid-posts were equipped with canvas bath, Persian cooler (a 20-gallon open-mouthed jar of porous earthenware), ice-chest, and one wheel stretcher, with lifter and hood apiece, and were open from May 5th to Sept. 16th. During this season these posts dealt with only 39 cases, since most cases were taken direct to a medical unit or dealt with temporarily by any medical officer in situ until removal could be effected.

*Consideration of Preventive Measures.*

With regard to the provision for future hot seasons—

(a) A large proportion of cases being due to the direct effects of the heat upon hospital patients with weakened constitution, it is essential to protect roofs and walls of hospital wards from the sun as much as possible and to provide electric fans freely. Much is already done in this way, but a final survey, before the season begins, might always reveal details requiring further action.

(b) Every case in hospital during the hot season should be examined for malaria and should take quinine if positive.

(c) With regard to healthy troops, it should be brought home to every man that constipation is dangerous, and medical officers in charge of units should be specially warned to pay attention to this habit.

(d) The occupations of those attacked in the afternoon suggest that a further warning is required with regard to fatigues and movements in the sun. Seasoned officers still frequently consider it manly to defy the heat, both in regard to clothing and duties. The late Sir Victor Horsley, here in Amara, paid for this heresy with his life. Greater folly and cruelty cannot be imagined. It may be generally stated that with a wet-bulb temperature of 80° hard physical work is impossible; at 90° all work is impossible; and at 95° life is impossible.

#### *Consumption of Water: Clothing.*

(e) The facts that the effect of heat must depend upon the loss of heat from the body, that this depends on evaporation and this again on the amount of water consumed and clothes worn, require further bringing home to all ranks. The consumption of water should be pushed. Men should be encouraged to count the number of half-pints of fluid they drink in the day, and in the hottest weather this should not be less than 16 (a gallon), and may be as much as 50 (three gallons) or more without harm.

(f) Similar emphasis and publicity require to be given to the question of clothing during the hot hours. The wearing of coats and belts should not even be optional; it should be forbidden. Puttees retain much heat, and thin stockings should be substituted. Shirts should always be worn outside shorts or trousers when working or marching; this at once doubles the body surface available for loss of heat, and adds greatly to the men's comfort. The adoption of a shirt-tunic to be worn in this way would be ideal for the hot weather. The blouse is already uniform in certain Indian regiments, and is worn in this way by their British officers. Its only faults are that it is too thick, and that it is not open at the neck. Finally, shirts should be worn open at the neck although buttoned, and in case of officers tied to the level of the top button, with stud holes buttoned outwards. This gives a smart appearance and adds vastly to the comfort by allowing a free issue of steamy air from inside the shirt.

#### *Other Suggestions.*

(g) In varying the official hours of work according to the weather, all ranks should be encouraged to keep early hours in the evening, with lights out at 10 P.M. at latest. Officers and others cannot be expected to be as fresh to stand the heat of the next day with only five or six hours' sleep in the cool of the night; and influence in such matters is contagious. "Early to bed and early to rise" should be a rule.

(h) The notification forms should be slightly amended to give in future further and more precise facts on these lines; and if records on similar lines could be kept by the whole Force each year a large body of evidence would be obtained of very great practical importance for military operations—and, indeed, for civil life—in hot climates.

(i) Further evidence of value in this connexion would be obtained from readings in various comparable conditions in different huts, tents, and buildings by the kata-thermometer, which shows rapidly of cooling from the human body, and so gives the effective result of humidity and temperature combined. One of these instruments has recently been issued to the meteorological station. They should be under the charge, as here, of a medical officer with special physiological training and an inquiring turn of mind.

Hitherto the value of the different types of hut and tent has been estimated by the general sensation of a few workers and a few patients and by very few and occasional thermometric readings. The importance of the subject warrants a much more extended and systematic inquiry, and I submit that, so long as any medical officer can be spared from hospital-work, an officer with special physiological training should be instructed to make a comprehensive inquiry on these lines throughout the Force, say during the months of June and July.

These suggestions appear to be the logical conclusions of Eastern experience and Western theory. In essential they have already for the most part been officially adopted. It is up to every M.O. in the Force to do his utmost to secure the carrying out of every detail.

## A NOTE ON *B. INFLUENZÆ*, ESPECIALLY AS REGARDS THE QUESTION OF "CARRIERS."

BY SHELDON F. DUDLEY, M.B., B.S. LOND.,  
SURGEON LIEUTENANT-COMMANDER, R.N.

BETWEEN Oct. 1st, 1918, and March 31st, 1919, 368 cases of influenza were treated in H.M. Hospital Ship *Agadir*. These cases came from 110 different ships or establishments at Scapa Base; as a result nearly every type and variety of the disease was seen, from the mildest to the most virulent. Descriptions of the pandemic one read of elsewhere and at first could not agree with often became explicable on admitting a fresh batch of cases.

#### *B. Influenzæ.*

As was the case a few years ago with the meningococcus, it is essential to state on what characteristics the organism one calls *B. influenza* was identified. Colonies on Matthews's medium<sup>1</sup> were circular, translucent, and brownish by reflected light; isolated examples often exceeded 4 mm. in diameter. Films from these colonies stained well with carbol-fuchsin, showing a Gram-negative bacillus that varied considerably in its morphology; some strains would show quite long filaments. Subcultures (if they grew at all) on to blood-smeared agar reverted to the text-book pin-point colonies, with the usually described characters of Pfeiffer's bacillus. On plain agar there was never any growth. As noted by Fildes and Baker,<sup>2</sup> using other media, stained films from a four- or five-day-old culture on Matthews's medium produced a peculiar granular debris with few distinct morphological bacteria. The differences in shape, size, and staining of bacilli, and the slight variation in the appearance and emulsifying properties of the colonies indicate that the bacteria which possess the above characters have different strains or are a group of organisms comparative to the Gram-negative diplococci.

#### *Culture Media.*

A probable reason why Pfeiffer's bacillus has not been invariably found in the late pandemic is the difficulty of being certain of the media and not realising this difficulty. Experiences in this ship with many medias found Matthews's to be the only really satisfactory one of those tried. I do not mean that Matthews's is better than the other medias used by other workers, but that owing to some unknown error in technique or materials satisfactory results were not obtained with other media in this ship. For example, 10 different strains of *B. influenza* which grew well on Matthews's media were planted on (1) blood-smeared agar, with the result six grew; (2) boiled blood-water agar—four grew; (3) a bad batch of "K" media<sup>3</sup>—none took; (4) blood boiled in agar—none took; (5) a media consisting of a killed, week-old culture of *Staphylococcus aureus* in blood broth added to agar—in this latter medium all the strains grew, but though in my hands this medium was the most satisfactory after Matthews's, it was not as good as the latter, as the following shows. *B. influenza* was isolated from the naso-pharynx from 10 men using Matthews's medium, whereas with the staphylococcus medium *B. influenza* was only recovered three times from the same 10 cases. In May and June, 1918, I tried to isolate *B. influenza* from various patients, using blood-smeared agar, but did not get a single success. I therefore very foolishly stated that I did not believe *B. influenza* was present in these cases. But I am now convinced if I had been using Matthews's medium they would have been found.

#### *Direct Smears of Discharges.*

The case against Pfeiffer's bacillus as a causative factor in influenza is often supported by the absence of predominant morphological influenza bacilli in stained smears from the patient's discharges. From 12 positive cases plates were inoculated and at the same time smears of the naso-pharyngeal mucus were stained with polychrome methylene blue and also carbol-fuchsin. In the plates from five cases the colonies of *B. influenza* predominated; in the corresponding stained smears numerous morphological *B. influenza* were seen in three instances, but in the other two one would not have liked to say they were present without the confirmatory evidence of the plates. On the remaining seven

<sup>1</sup> THE LANCET, July 27th, 1918.

<sup>2</sup> THE LANCET, Nov. 23rd, 1918.

<sup>3</sup> Ibid.

plates many colonies of the organism appeared, but in only one of the corresponding films were *B. influenza* at all evident. In all the stained smears except three, where organisms of any kind were scarce, numerous other bacteria were present complicating the picture. Hence, because *B. influenza* is not obvious in stained films of a patient's discharges it does not follow it will not grow luxuriantly on culture.

#### Carriers of *B. Influenza*.

There were many cases of influenza continually on board from October to the middle of March, when the number steadily diminished, until at the end of April only two mild cases remained in the ship. During this period the nursing staff of the ship were all examined as regards the presence of *B. influenza* in the discharges from the naso-pharynx.

1. On Dec. 5th-7th	21 men produced 19 positives, 90 per cent.
2. " March 13th-15th	22 " " 19 " 87 "
3. " " 27th	20 " " 10 " 50 "
4. " April 27th	22 " " 6 " 27 "

Sixteen of the men were swabbed on all four occasions, representing a positive result as + and absence of *B. influenza* as -. We can classify them thus in the order of the above dates.

4 men ... .. + + + +	4 men ... .. + + - -
4 " ... .. + + + -	1 man ... .. + - - -
1 man ... .. + - - -	2 men ... .. - - - -

This shows the infection died out fairly evenly in the nursing staff as the cases of influenza got fewer.

The mercantile crew of a hospital ship has quarters completely separated from the nursing staff, and are, of course, allowed no communication with the patients. A few of the crew were swabbed for comparison with the nursing staff.

10 men on Dec. 6th	gave 6 positive results.
12 " March 28th	2 " "
10 " April 27th	1 " "

As regards the incidence of influenza among the ship's company, 40 per cent. of the mercantile crew got infected (average strength 52 men); 62 per cent. of the medical staff had clinical influenza (29 men). The whole 29 of the medical staff were examined at one time or another, and 26 were proved to be "carriers." Of the 3 who were negative, 2 had had influenza and the other was a medical officer who joined when the epidemic was practically over. Of the positives 14 never had clinical influenza previous to the first positive swabbing, though 4 subsequently developed it. Of 12 who had had "flu" 2 got it again later.

By the courtesy of Surgeon-Commander H. S. Burniston, C.M.G., I was allowed to examine 20 seamen and stokers of *H.M.S. Revenge*. Four (20 per cent.) were positive "carriers." The ship's company of *Revenge* averaged about 1200 men. In May, 1918, 22 per cent. had clinical influenza; in October 21 per cent. got the disease (including roughly 3 per cent. of those who had had it in May). Thus about half the ship's company had had influenza. Of the 20 men swabbed 15 had never had clinical influenza, and only 1 of the 4 men who were "carriers" had had it. The latter 4 cases were all from widely separated parts of the ship. It may be guardedly presumed, therefore, that about one-fifth of the crew, or 240 men, were harbouring *B. influenza* in the naso-pharynx on Dec. 11th, a month after the last clinical case had occurred on board on Nov. 9th.

#### Secondary Infections.

Practically every pathogenic organism has been reported as present in the late pandemic. The experience was the same in the *Aqadir*—pneumococci and streptococci are the most obvious secondary infections; but *B. typhosus*, meningococci, diphtheria bacilli, and many unidentified bacteria were seen. This ship may be said to have dealt with about 100 different isolated outbreaks of the disease, each of which often seemed to have its own clinical and bacterial picture. For example, at Scapa in October and November the broncho-pneumonias were nearly all pneumococci, as proved by cultures from the blood and pleural fluids of the patients, and these cases tended to be delirious and terminated by crisis. By February streptococci had to a great extent replaced the pneumococci. The patients remained clear-headed to the end and the temperature swung considerably before settling down. It was not until the advent of the streptococcus that the typical cyanosis and pure blood expectoration (that one read of down South) became evident at Scapa. To give another example, though 8.3 per cent. of the total cases had epistaxis, in 19 cases from one ship, which were all mild in other respects, 9, or 47 per cent., had epistaxis.

#### "Filter Passers."

Considerable evidence has been brought forward to prove that a "filter passer" is a causal agent in influenza. The most constant characteristic of this filter passer appears to be that of causing hæmorrhagic lesions in the lungs of experimental animals. Yet in the mild cases of influenza, which form the great majority of all cases, lung signs and even cough are often absent, and clinically hæmorrhage is really not common in influenza as a whole. Altogether the evidence suggests the world-wide spread of an organism, fairly harmless in itself, which prepares the way for any pathogenic organism that happens to be in the environment at the same time. And perhaps this harmless organism (*B. influenza*) especially favours the spread of a filter passer which, though extremely virulent in its presence, cannot gain a footing in the human organism without the help of Pfeiffer's bacillus. Since the above paragraph was first written A. Ortoni and Barbie<sup>4</sup> have reported that *B. influenza* and the filtered sputum from an influenza case are harmless to guinea-pigs separately, but together are extremely pathogenic. Should this observation be confirmed, it would go a long way towards proving the double ætiology of influenza as due to a filter passer plus Pfeiffer's bacillus.

During the time influenza was being treated on board, three or four of the ship's company complained of feeling out of sorts; they were not definitely ill, but suffered from headaches and sometimes felt shivery. One case of this sort two or three times had to be put to bed for a day or two. His temperature never rose above normal; his pulse, which was rapid at first, soon settled down to a rate of about 50 beats a minute. *B. influenza* was present in his naso-pharynx. This class of man, who never had clinical influenza, may well have been a chronic ambulant type. Many of the post-influenzal "neurasthenics" and "debilities" may possibly be chronic toxæmias due to the influenzal parasite, whether *B. influenza* or anything else.

If we grant *B. influenza* as a factor in the cause of influenza, "carriers" and missed cases such as "feverish colds" and chronic ambulant cases probably are more dangerous and numerous than the bed case. These, together with the short incubation period, serve to explain the tremendous rate of spread of the disease.

#### Individual Immunity.

In a ship where 50 per cent. of the ship's company may be infected in a week the rest must be temporarily immune. The crew of a battleship sleep under circumstances where cubic space is very limited and perfect ventilation very difficult. Influenza will spread in a ward with 10 feet between bed centres; with hammocks 2 feet apart, the chances of contact infection by spraying is 125 times as great as in the ward if head-to-foot "slinging" is not insisted on, and 15 times as great where it is properly carried out. (The danger of infection being inversely as the cube of the distance.) From these considerations it can only be individual immunity that protects those who escape infection in the close confinement of a ship. That natural immunity to influenza must vary considerably from time to time in an individual is suggested by the incidence of the disease among the nursing staff, 60 per cent. of whom had influenza. Though in close contact with the cases all the time they did not all get it together, as in the ordinary ship, but the cases were spread more or less evenly over six months. The effect of lowered vitality is well illustrated by the four medical men on board who contracted the disease. They had all been attending cases for one or two months before succumbing themselves. In each instance there was a definite cause of lowered resistance about 48 hours beforehand. In two it was the long journey between Scapa and the south; in one, a temperate man, a larger quantity of alcohol than he was accustomed to; in the last case a long walk after some weeks' confinement in the ship.

Before concluding, I should state the examination of the staff could not be carried to the logical conclusion when all were free from *B. influenza*, because the ship's company was relieved before this was possible.

Enough evidence, I think, is collected to make it worth while to investigate how many people in normal times harbour *B. influenza* in their naso-pharynx. Even if *B. influenza* should be proved a harmless saprophyte, and if carriers of it are rare when there is no epidemic, its almost universal distribution during an epidemic surely requires some elucidating.

<sup>4</sup> La Presse Médicale, May 8th, 1919.

# A STUDY OF THE ÆTIOLOGY OF THE "DESERT," SEPTIC, OR VELDT SORE AMONGST EUROPEAN TROOPS:

AND ITS ASSOCIATION WITH FAUCIAL DIPHtheria.

BY COLIN MCK. CRAIG, O.B.E., M.D. MANCH., D.P.H.,

LATE MEDICAL SUPERINTENDENT, MANCHESTER SANATORIUM,  
ABERGELE; LATE CAPTAIN, R.A.M.C.; O.C. MILITARY  
LABORATORY, E.E.F.

DURING the Egyptian and Palestine campaigns chronic sores, very resistant to local treatment, on uncovered parts, became a great scourge, especially amongst mounted units. I investigated these lesions in a field laboratory, established in connexion with this force in the desert, throughout the whole period and have had access to a very large amount of material.

Most observers are agreed that the "desert" sore is of distinct clinical type, that it is associated with peculiar geographical and climatic conditions, in no way connected with dermal leishmaniasis; and that it must be due to some specific organism. I am of opinion that this organism is the true Klebs-Löffler bacillus.

While my investigations were being undertaken a paper by Lieutenant-Colonel C. J. Martin, C.M.G., D.S.O., F.R.S.,<sup>1</sup> set forth the results of his examination of a limited number of cases amongst the Australian units, E.E.F. He examined hairs extracted from the vicinity of the lesion and noted diphtheroid organisms in this situation. Later he investigated one strain more thoroughly and found that it gave the typical reactions of the Klebs-Löffler bacillus. This particular case differed in no wise from the others and was associated with no obvious constitutional disturbances. He concluded that the diphtheria infection was superimposed upon some pyogenic coccal lesion.

## Clinical Characters of the Sore.

Under the term "desert sore" many sores have been loosely classed, which differ widely in their ætiology. The sore I refer to is invariably on exposed parts and mainly on those covered by hairs—i.e., dorsum of hands, forearm, around elbow and knee-joints, on lower part of thigh, and exposed part of legs. (At the commencement of the campaign mounted units, as well as infantry, were commonly clothed in drill shorts.) In a small proportion of cases the lesions occur on the face.

1. *The vesicle.*—The onset is sudden. The first appearance is one of acute inflammation round a hair follicle and in a few hours a vesicle forms full of clear straw-coloured fluid, varying from size of a pea to half an inch or more in diameter. The pain is at first quite out of proportion to size of lesion. It soon bursts and exposes the deeper layers of the cuticle, thus forming a shallow ulcer.

2. *The primary shallow ulcer.*—In the early stages the base is dry, red, and glazed. It is acutely sensitive. In a considerable proportion a thin pearly-grey membrane may form, though its absence does not indicate a non-diphtherial origin. The edges of the surrounding skin become undermined and the ulcer commences to spread peripherally.

3. *The chronic stage of the ulcer.*—The appearance is quite characteristic. It is punched out and circular in outline, with undermined edges and thickened margins. The base of such an ulcer is covered with grey-coloured debris, beneath which one can frequently determine a tough and adherent membrane. Such a deep ulcer may discharge little or no pus.

## Methods of Investigation.

Scrapings were taken from the spreading edge of the ulcers by a sterile knife and inoculated directly on to freshly prepared Löffler's serum. In unbroken vesicles the skin was first washed with alcohol; the vesicle was then ruptured and the fluid mopped up from the base, then inoculated on to medium by a sterile swab. The base was also scraped.

## The Results of Primary Culture.

One hundred and ninety-seven sores were investigated. The micro-organisms constantly present in the cultures were: (1) staphylococci (*S. albus*), rarely *S. aureus*, or *S. citreus*; (2) diphtheroid bacilli, of two morphological types, i.e.:—

(a) A small straight bacillus, staining uniformly with methylene-blue, Gram-positive but decolourising with ease,

showing no polar differentiation with Neisser's stain. Usually these small forms were present in moderate number and lay parallel in pairs.

(b) Forms morphologically identical with the true Klebs-Löffler bacillus.

I believe that type (a) is an immature form of (b). Inoculation experiments showed that the small form was equally as toxic as the large and developed into the latter.

One or other of these types was present in 129 out of 197 sores examined—67.5 per cent. I consider this percentage high when the following facts are considered. (1) In the chronic stage of the sore the bacillus is in scanty numbers and attenuated. (2) The frequent dressing of sores with anti-septic lotions. (3) With further cultures the positive findings would probably have been higher. (4) The positive findings compare favourably with results of swab culture of clinical diphtheria of the throat, especially under field conditions.

The following are the statistics of examination of swabs for Klebs-Löffler bacilli in this laboratory for two months in 1917:—Total examinations, 5442. Klebs-Löffler bacilli in throat, 455 (8.3 per cent.); diphtheria carriers, 34 (0.6 per cent.); contacts, 49 (0.9 per cent.).

## Association of Sores with Faucial Diphtheria.

During the period of investigation diphtheria both of throat and nose had been prevalent amongst the troops. The epidemic was distinguished by (a) the mildness of the average case; (b) the difficulty of tracing the source of infection. The question was to decide whether the diphtheroid bacillus in the ulcers was identical with the organism found in the throat.

The evidence I collected at that time may be stated as follows: there is a close correlation between the incidence of faucial diphtheria and the occurrence of the "desert" sore, the causal agent in each case being the true Klebs-Löffler bacillus.

The common occurrence of diphtheritic skin lesions under tropical conditions, as compared to their rarity in temperate climates, may be explained as follows: (a) by moistness of skin and activity of sweat glands, soddenness of epithelium providing an opportunity for entrance of bacilli and a suitable medium for their multiplication; (b) by the environment of the troops—close contact between man and man, lack of washing facilities, and constant liability to laceration of skin.

The clinical evidence I have collected in favour of this view is interesting and suggestive.

## Association of Sores with Constitutional Disturbance and Toxic Neuritis.

The question arose as to why constitutional disturbances and paralysis of the throat or limbs had not been observed. My contention is that cases of paralysis had occurred, and were, occurring, but that either they had been overlooked or attributed to a presumably untreated faucial diphtheria. [Cases were here cited of specific instances of typical diphtheritic paralysis occurring in association with "desert" sores.] Evidence on this score will also be found in a paper written after this work was completed by Major F. M. R. Walshe,<sup>2</sup> in which he described a large number of cases of paralysis following "desert" sores, in one series in 27 per cent.

Medical officers all appear impressed by the amount of debility and weakness, especially of the limbs, which is associated with these ulcers, and quite out of proportion to the size, number, or extent of the lesions. The amount of military inefficiency was considerable, as these debilitated men were the first to fall out during the heavy desert marching. The muscular weakness was probably due to chronic absorption of the toxins in an amount insufficient to cause paralysis.

## Confirmatory Bacteriological Tests.

The first experiments on animals were made with glucose-broth cultures of the small diphtheroid organism obtained from a "desert" sore. The organisms were stained uniformly and showed no polar differentiation. 2 c.cm. of the broth culture were then inoculated subcutaneously into a guinea-pig weighing 300 g. The animal died in 48 hours, and from the necrotic tissue at site of injection typical polar staining Klebs-Löffler bacilli were obtained.

Six strains of diphtheroid bacilli isolated from throat lesions and five from "desert" sores were submitted to animal and biochemical tests. All the strains produced acidity in glucose broth after 48 hours' incubation. Both

<sup>1</sup> Brit. Med. Jour., June 9th, 1917.

<sup>2</sup> THE LANCET, 1918, II., 232.

cultures of the strains in doses of 2 c.cm. were injected subcutaneously into guinea-pigs of approximately the same weight. Eleven control animals were given a similar dose of the organism with the addition of 1 c.cm. of diphtheria antitoxin. [The results were here set out in tabular form. Of the five strains from "desert" sore, the injected animals died in 24 hours, 24 hours, 36 hours, 24 hours, and 30 hours respectively. All the controls lived. Of the six throat strains, five died in 36 hours, 48 hours, 80 hours, 36 hours, and 60 hours respectively; the sixth animal was ill, but recovered. All the control animals lived.]

*Post-mortem appearances of injected guinea-pigs.*—At the site of injection there was intense congestion and oedema of surrounding tissues; in those animals which survived for more than 24 hours also membrane formation. In all animals an abundant straw-coloured effusion was found in the pleural, pericardial, and abdominal cavities. The suprarenal capsules were swollen, plum-coloured, and intensely congested; section showed hæmorrhagic changes. The spleen, pancreas, liver, and other viscera appeared normal. Klebs-Löffler bacilli were recovered on culture in every case from the site of injection—that is, from the necrotic tissue. Similar cultures from the heart's blood proved sterile, showing death from toxæmia.

All these typical post-mortem appearances agreed with the classical description of the action of the Klebs-Löffler bacillus upon these animals.

The tendency to the production of serous effusions by diphtheria toxins would explain the vesical formation of the primary cutaneous lesion and the suddenness of the onset of the "desert" sore.

A striking experiment was performed on quails, a bird apparently very susceptible to the diphtheria bacillus. Birds were selected after two months in captivity and in very good condition. 2 c.cm. of a broth culture of a typical diphtheria bacillus isolated from a "desert" sore were injected into the pectoral muscles of one bird; a second was given a similar dose mixed with 1 c.cm. of diphtheria antitoxin. The first bird died in 16 hours; the second exhibited no symptoms. Considerable serous effusion found at site of inoculation, from which the bacillus was recovered; heart's blood was sterile.

I conclude that the diphtheroid organism isolated from "desert" sores can be none other than the true Klebs-Löffler bacillus. The question may be raised why are not the cutaneous lesions more frequently associated with membrane formation and constitutional disturbances. The answer is that only a very small percentage of positive throat cases presented lesions or constitutional disturbances such as are commonly associated with clinical faucial diphtheria. Out of a series of 221 positive cases I examined clinically only 10·8 per cent. presented such symptoms.

#### *The Results of Antitoxin Treatment.*

Diphtheria antitoxin proved an absolute specific for the chronic "desert" sore of the type described. This will be supported by the experience of a large number of regimental medical officers, medical officers in field ambulances and casualty clearing stations. The sores which have resisted treatment for weeks and months heal in a few days with an average dose of 4000 units. Critics have suggested that the normal horse serum would have the same effect. Antidysenteric serum (horse serum) had a partial protective influence, the animals recovered, but suffered considerably nevertheless. The natural deduction is that horse serum normally contains a certain amount of antitoxin to the diphtheria bacillus.

#### *Prophylaxis: General and Personal.*

*General prophylaxis.*—I am convinced that the human carrier cannot account for the prevalence of diphtheria during this campaign. The bacillus is capable of a saprophytic existence. I suggest that one medium is horse manure. From horse manure I isolated a diphtheroid bacillus morphologically identical with the Klebs-Löffler, but non-pathogenic to guinea-pigs. Since the troops have advanced into the cultivated portions of Palestine the incidence of "desert" sores has fallen to a negligible quantity. These facts, with the greater incidence of "desert" sores amongst mounted units suggest an intimate connexion between horse manure and the causation of throat diphtheria and "desert" sores. I would suggest further investigation on these lines.

*Personal prophylaxis.*—The measures suggested are the protection of exposed parts of the body, and especially the

knees, from injury; the wearing of "shorts" by mounted units is unsuitable. The use of antiseptic lotions to the arms and knees of the men, and especially to any abraded surfaces, is to be advocated wherever possible, as well as protection of sores with a dressing, and the avoidance of too intimate a contact between man and man.

#### *Conclusions.*

1. That this "desert" or septic sore is a distinct clinical entity and has a distinct geographical distribution.

2. That the ætiological factor is the Klebs-Löffler bacillus, which is responsible for the specific characters of the lesion.

3. That this organism possesses a low virulence, and therefore only produces constitutional disturbances in specially susceptible individuals.

4. That under favourable conditions these sores may be responsible for outbreaks of faucial diphtheria.

Against these conclusions certain objections raised are:—

1. That the diphtheria bacillus is but a secondary infection superimposed upon some pyogenic lesion. The frequency with which I have isolated the Klebs-Löffler bacillus from the primary lesion with appropriate technique shows that it is a primary infection.

2. The inability of pathologists at the base hospitals to find Klebs-Löffler bacilli in the majority of these sores. The more chronic the sore, the greater the number of pyogenic organisms present, the more difficult it is to isolate the Klebs-Löffler bacillus. Also in base hospitals a large proportion of these cases were deep-seated pyogenic infections with which I was not dealing. In this way I explain the discrepancy between my results and those published by Warren Crowe.<sup>3</sup>

3. The question of the curative action of antidiphtheritic serum I have dealt with.

I desire to place on record my indebtedness to Major A. R. Ferguson, R.A.M.C., for enabling me to carry out part of this work in his laboratory. My thanks are also due to Captains P. H. Bahr, T. J. Mackie, R.A.M.C. (T.F.), F. Standish, R.A.M.C. (T.F.), and J. G. Willmore, R.A.M.C. I wish also to thank Captains Higgins, R.A.M.C., and C. Newton-Davis, I.M.S., for providing me with clinical histories of their cases.

## COMPULSORY INOCULATION AGAINST SPANISH INFLUENZA.

By FRANCIS TEMPLE GREY,  
SURGEON-LIEUTENANT, ROYAL NAVY; O.C. SAMOA RELIEF  
EXPEDITION, 1918.

My experience in the South Sea Islands so impressed me with the value of antipneumostreptococcal inoculation as a prophylactic against Spanish influenza that on my return in February, 1919, to Australia (where the scourge had already got a hold in Melbourne, but had so far been kept out of Sydney) I urged the importance of making it compulsory. But outside the Service nothing happened.

The following preliminary communication submitted early in March to a semi-scientific periodical was published six weeks afterwards.

"The vaccine prepared by the Commonwealth Serum Laboratories has in my hands achieved results which are nothing short of miraculous. As a result of my experience, I urge compulsory inoculation on the first signs of the appearance of epidemic influenza in any community as the one efficient means of tackling the scourge; inoculation to be repeated every month or six weeks. I claim that this measure will (1) decrease enormously the incidence of the disease; (2) mitigate its severity; (3) reduce the mortality to a low figure.

The following evidence in support of my recommendation is, to say the least of it, impressive.

(1) The entire ship's company of the man-o'-war which took my expedition to the islands were inoculated. Communication with the shore at the various ports was, as far as possible, avoided, but this ideal was not entirely attained. Not one case developed.

(2) Every member of my expedition was inoculated at least four times in three months. Not a single case developed, although the risk of infection was no small one, when it is remembered that in Samoa alone one-fifth of the entire population was wiped out by the scourge. Two officers had an illness of four to five days not as severe as the so-called influenza of normal times.

(3) An interesting experiment to test the efficacy of the vaccine was provided by the Governor of American Samoa, who sent, against the wishes of British Samoa, 40 natives from Pago Pago (a clean port) to Apia during the progress of the epidemic. These were isolated, inoculated, and not released until judged to be in a positive phase. Not one contracted the disease, and the Secretary of Native Affairs, who knew their names and villages, reported all clear after a lapse of one month.

(4) Ship's company and passengers of the steamer which brought the expedition from Suva to Sydney were inoculated without exception. We anchored in quarantine in Sydney, and on the second day a case was taken ashore. We remained on board, quarantined another week. Although the ship was very overcrowded not another case developed.

(5) The naval dépôt at Williamstown contains a floating population of about 500, half of whom live on shore, and the rest, of course, have a fair amount of shore leave. All hands have been inoculated twice in the last three months. There have been only 15 cases, all mild except two, and no deaths.

The severe reaction in some cases to the lymph during the small-pox epidemic of 1913 on an unvaccinated adult community has done much harm to what must perforce be called the 'cause' of vaccination in Australia, seeing that the public has been taught nowadays that it is entitled to an opinion on subjects it knows nothing about. It may reassure these opinionated objectors to know that in this case, at any rate, there is little or no reaction. I myself have seen only one reaction in all my inoculations.

Conscientious objectors, if the legislature has not the courage to compel inoculation, should be isolated from the rest of the community, it being pointed out to them that we object not so much to their committing suicide as to their carrying the disease unmitigated to those who are not tired of life.<sup>22</sup>

In the middle of March, a fortnight after my first communication was submitted, an epidemic broke out in the ship referred to in paragraph 1, and by the end of the month there were about 100 cases with no deaths. Inoculations (end November and end December) appear, therefore, to have given immunity up to the middle of March, and, when the disease broke through, to have rendered it non-fatal. To deny mitigation by inoculation in this case is to say that the disease was not Spanish influenza (which has a high mortality), and, therefore, that the immunity was absolute.

Soon after my first communication was submitted an influenzoid epidemic broke out in the naval dépôt at Williamstown, and within a fortnight we had 100 cases (characterised by high infectivity, extraordinary mildness, and an average age-incidence of 18½). I was inclined to regard this as a separate clinical entity, but if it were Spanish influenza then the case for inoculation is rendered stronger than ever.

From the beginning of the year to date (June 20th, 1919) 2875 ratings have been vaccinated at the dépôt; there have been 345 cases of influenza, 5 with pneumonic signs, and no deaths.

#### *The Constituents of the Vaccine.*

A full dose of the vaccine used by me contains 125 millions of *Micrococcus catarrhalis*, 50 millions each pneumococci, streptococci, and of a Gram-positive diplococcus. My experience shows Pfeiffer's bacillus to be unnecessary as a constituent of a vaccine directed against this epidemic, and, in view also of the risk of a negative phase, it is clearly unwise to use it in any community where the epidemic is already well under way.

If Spanish influenza be caused by a streptococcus for which the way has been prepared by, say, the bacillus of Pfeiffer or a filter passer, and especially if this last represent a stage in the development of the streptococcus, an anti-streptococcal vaccine should be, and in my experience has been, competent to protect.

On May 14th half the dépôt were given a pure anti-streptococcal vaccine and the other half were given the vaccine already mentioned, with a resulting difference in incidence to date of practically nil.

Immunity begins to peter out after the fifth week. I give a full dose (50 millions each pneumococci and streptococci) every five or six weeks, and never get more than the mildest reaction. I do not inoculate children or the old unless requested, as these appear to have relative immunity. The disadvantage, from the public point of view, of a preliminary dose, apart from the fact that it is unnecessary, is that the public are apt to

think that the preliminary dose is all that is required, and for this and other reasons (if reasons they can be called) do not come up again, and their non-immunity is charged against inoculation. The theoretical objection to a full dose without preliminary—viz., that in stray cases a focus of chronic suppuration may be lit up or that a nephritic may stand it badly—has no weight against the foregoing consideration, and is in any case the concern of the individual vaccinator, who, if ignorant, will damage this as he has damaged other causes.

I have to acknowledge with grateful thanks the help and encouragement I have received from Surgeon-Captain Eames, R.N., Director of Naval Medical Services (Australia); his predecessor, Surgeon-Commander Bean, R.N.; Surgeon-Lieutenant Commander Ramsay Smith, R.A.N., in medical charge of the naval dépôt, Williamstown; and especially from Dr. Penfold, director of the Commonwealth Serum Laboratories.

## A CASE OF "606" DERMATITIS TREATED WITH INTRAMINE, WITH SUBSEQUENT MULTIPLE SUBCUTANEOUS TUMOUR FORMATION.

BY A. R. FRASER, M.D. ABERD.

THE following case of exfoliative dermatitis occurred in my wards at the Scottish Command Central Venereal Hospital, Robroyston.

#### *Account of Case.*

The patient was a recruit of six weeks' service, attached to a labour company, aged 41, a healthy man, but undersized and slightly and slimly built, with a large double inguinal hernia. His medical category was B2. He had no history of previous venereal disease. He was admitted to hospital with a large spirochætal chancre of three weeks' duration. This was a diamond-shaped erosion, with a moist, greyish, finely granular surface. Very definite induration could be made out between finger and thumb. It was somewhat larger in size than a sixpenny-piece, and was situated on the upper external aspect of prepuce. There was a marked inguinal, axillary, epitrochlear, and posterior cervical adenitis. A scattered, diffuse, irregular, fairly symmetrical faint macular rash was present over the trunk and flexor aspects of limbs, being, however, most marked below the scapular angles. The fauces were somewhat injected, but there was no other mucous membrane lesion. Lungs, heart, and the central nervous system showed nil abnormal. Spirochæta pallida was found present in the sore on the day of admission, and two days later his Wassermann reaction gave a strongly positive result (++).

He was then put on a course of neo-kharsivan intravenously, and mercurial cream (metallic mercury) intramuscularly. On the day of his third injection the sore had completely healed, having meanwhile been locally treated with calomel ointment, 30 per cent. Seven days later the rash had disappeared and except for a slight adenitis the patient showed no active signs of lues. His course consisted of 3.90 g. neo-kharsivan intravenously, and gr. 7 metallic mercury intramuscularly, extending over a period of 56 days. This he underwent without incident, on no one occasion showing the slightest reaction. His urine was free from albumin throughout the course. On the fifty-eighth day his Wassermann reaction gave a complete negative result. He was forthwith discharged from hospital.

On the morning of his discharge, having drawn his kit and prepared for the journey to his dépôt, he complained to me of having a headache and generally feeling off colour. On examination it was found that a scarlatinial eruption had appeared over both forearms on the flexor aspect. His temperature was 102° F. He was readmitted to the ward and put to bed, and adrenalin 1:1000 administered in 10 m. doses every four hours. This occurred on the sixtieth day. Calomel gr. 5 followed by a saline was given. The following day the rash had spread over the face and neck, legs and trunk. It was well marked on the forehead. At this stage the rash might have passed for scarlet fever, but later blebs and pustules developed, with scaling and crusting on their rupture. There was very considerable exudation into the skin, most marked on the face and head. The cheeks and eyelids became very swollen and puffy, the eyes practically closed. The temperature remained at 102°. The patient was put on ichthyol m. 5 in cachets, three being given daily. The application of calamine cream and bran bathing failed to diminish appreciably the intense skin irritation. By the fourth day the rash had become confluent, particularly over the thighs and abdomen. The tongue was dry and very heavily coated; it was difficult to induce the

patient to take even a little milk, and he was losing ground rapidly from loss of sleep. He complained most of pain in the eyes, and a dry, congested, choking feeling in his throat. Swallowing was obviously a trying and painful procedure. Ichthyol was continued until the eighth day, but no improvement could be seen from its employment. It was discontinued. On this day 2.50 c.cm. intramine was given intramuscularly. The following day the temperature dropped to 99.4°, the patient expressed himself as feeling better, and exfoliation commenced over the face and forehead. There was no pain at the site of injection, and no local reaction. Exfoliation continued, and four days later a second injection of 2.50 c.cm. intramine was given, again causing no local pain. The skin exudation had now gradually subsided and exfoliation had continued apace. A third and fourth injection of intramine in similar doses followed at four-day intervals, and the patient steadily improved. The skin had now become of an intensely reddish-brown tint and the itching was very severe. This gradually subsided and the skin became very thin and atrophic and of a deeply pigmented dull coppery hue. The patient's general condition steadily improved, his voice was stronger, he became interested in his surrounding, his appetite improved, and he became much less depressed.

On the twenty-seventh day a very large non-inflamed swelling appeared suddenly at the lower end of the sternum in much the same manner as a pyæmic abscess. By evening it had reached the size of a cricket ball. There was no surrounding inflammation and no "pointing." The following day similar smaller swellings had appeared over the external condyle of the left femur, the upper third of the left fibula, over the symphysis pubis, the upper third posterior aspect right thigh, the external surface upper third of the right tibia, the left epigastrium, the back of the left elbow, and on the sacrum. They varied in size from a walnut to a large plum. These were fluctuating, non-inflamed, painful swellings. They seemed peculiarly tender, ordinary gentle palpation being resented by the patient. The contents proved to be a thick gelatinous, slightly opalescent, stringy mucinoid substance which was very difficult to draw into a syringe, even through a needle of large lumen. There was no pus. Microscopically it showed no pus cells and no organisms present. An occasional epithelium cell could be seen. No organism could be cultured. Although the patient's general condition improved, these swellings continued to appear, until by the fifty-first day they had reached a total of 72. In every case the swelling increased in size, remained for two or three days, eventually burst, and healed over in 24 hours without a scar. The patient steadily lost weight, but otherwise maintained his general condition. He did not look ill, and his voice was that of a strong, healthy man.

The tumour formation continued without abatement, and owing to lack of nursing facilities he was now transferred to a general hospital. There he lost ground insidiously, and the case terminated fatally a few months later. The post-mortem findings coincided with that condition described as acute yellow atrophy.

#### Conclusions.

It is extremely difficult to suggest any definite cause for this extraordinary process of tumour formation. Pyæmic abscesses containing definite pus occur in severe cases of "606" dermatitis. Here, however, the absence of pus and the sterility of the tumour contents, together with the non-inflammatory nature of the swelling, makes it extremely difficult to draw any analogy. The process seemed to be of the nature of a subcutaneous myxomatous degeneration. In all probability salvarsan was the exciting cause. There seems nothing to suggest that the intramine was in any way responsible for the condition. On the contrary, I think this drug was beneficial, and essentially non-toxic.

The immediate improvement following the administration of intramine was very marked. The fall of temperature, the early exfoliation and the appreciable improvement in the general condition coincided with the first and second intramine injections. In spite of the patient's very poor cachectic condition its intramuscular administration caused no pain or discomfort whatever.

Although no such condition has been described, it seems a possible suggestion that his syphilis was in itself the exciting cause. One feels, however, that this is unlikely, since his disease had reached a "latent" condition. It is extremely probable that in both "606" jaundice and dermatitis the benzene or amino group, and not the arsenic, is the causative agent, and as this condition has never been observed as caused by arsenic apart from this chemical combination, the amino radical may also in this case have been the causative agent.

Aberdeen.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### THREE UNUSUAL CASES OF INTESTINAL OBSTRUCTION.

BY W. H. C. ROMANIS, M.B., M.C. CANTAB.,  
F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL; SURGEON, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

INTESTINAL obstruction may justly be regarded as one of the more interesting forms of acute abdominal disease, both from the point of view of the diagnosis of its cause and no less from the consideration of the various problems involved in its surgical treatment. The three cases recorded below are not only instances of obstructions from rare causes, but one at least presented a complex problem in surgical treatment.

CASE 1.—A woman, aged 45, after some weeks of ill-health and constipation, was suddenly seized with acute abdominal pain and vomiting, which rapidly became dark and evil-smelling. When seen four days later the pain and vomiting were unaltered, the abdomen was very distended, and visible coils of bowel were present, especially in the right iliac fossa, where a large, resonant, rounded mass was present. The bowels had not been opened for four days, and her pulse and general condition were poor. Laparotomy was performed, and the first organ that presented itself was the cæcum, distended to a diameter of 7 inches and completely green and gangrenous, the gangrene extending up the colon to the hepatic flexure. All the intestines were very distended, especially the large bowel, and low down in the pelvic colon was a small movable ring carcinoma causing complete obstruction; the cæcum was in no way twisted, and had evidently become gangrenous from the tension of its walls caused by its distended condition. The gangrenous cæcum and ascending colon were removed, but the patient's condition was not sufficiently good to permit of the growth (which was operable) being also resected, while the distended and friable condition of the bowel rendered any attempt at an intestinal anastomosis hazardous. Paul's tubes were therefore tied into the lower end of the ileum and the upper end of the ascending colon and the abdomen closed. The patient made a rapid and uninterrupted recovery, was not troubled with soreness and digestion of the skin round the enterostomy wound, and gained weight. Some weeks later the growth was resected and a double anastomosis done, the two ends of the pelvic colon being united by end-to-end suture and the divided end of the ileum implanted in the side of the transverse colon.

CASE 2.—A woman, aged 62, was admitted with a history of no previous ill-health, but of five days intense pain and vomiting of sudden onset. The bowels had not been opened and the vomiting was incessant, and consisted of black and foul-smelling matter. The abdomen was very little distended, but visible intestinal coils were present, and in the left iliac fossa a round and very hard movable mass the size of a large chestnut could be felt. It was thought that this was probably a ring carcinoma causing the obstruction. The abdomen was opened and a large gall-stone was found firmly impacted in the ileum 2 feet above the ileo-cæcal valve. The bowel above was extremely distended, and the condition of its wall at the point where the stone was and for a foot or two above was very bad, and gangrene appeared to be imminent. The stone was extracted through an incision in the bowel wall, the bowel resutured and covered with an omental graft, the patient recovering rapidly. Examination at the time when the abdomen was opened showed that no further gall-stones were present, but there were many old adhesions round the gall-bladder and duodenum, though on inquiry afterwards the patient stated that she had never had any pain or symptoms that could in any way have been caused by the presence of gall-stones.

From these two cases it appears that distension of the bowel alone without any direct strangulation of its blood-supply can, if allowed to continue long enough, go beyond the stages of congestion, œdema, and infiltration of the bowel wall, and lead to actual gangrene of the whole thickness of the intestine. Perforation of stercoral ulcers in the distended colon above an obstruction is by no means uncommon, but distension-gangrene of the whole cæcum is a considerable rarity.

CASE 3.—A soldier, aged 20, was admitted with a history that 14 hours previously he ran a seven mile race, and for 12 hours had had acute abdominal agony of sudden onset, with intense vomiting. His bowels had been well opened, and on examination his pulse was 70, his abdomen retracted, board-like and dull in the flanks. Laparotomy was performed at once and the abdomen was found full of a blood-stained purple fluid, a large number of black gangrenous coils of ileum, in places already turning green, presenting themselves. It was found that many feet of ileum had passed through a small hole in the lower part of the mesentery, and that not only was the portion of howel that had passed through the mesentery gangrenous, but the pressure had produced gangrene of that part of the ileum in whose mesentery the aperture was, the gangrenous portion extending down to within 2 inches of the cæcum. The whole gangrenous portion was resected almost down to the cæcum, the ends closed, and a lateral union made with two layers of silk sutures between the lower end of the ileum and the side of the cæcum. On subsequent examination the resected portion was found to consist of 14 feet of ileum, all black and gangrenous, but the patient was too bad on the table for any investigation as to the amount of ileum remaining. He made an uninterrupted recovery, and after the first week rapidly put on weight until in four weeks he was heavier than before the operation. At first there were six or seven loose motions daily, but when seen four months after the resection, he was having two soft motions daily and doing his full day's work with ease.

#### Other Recorded Cases.

There have been many and prolonged controversies as to the amount of ileum necessary for the maintenance of normal nutrition. Probably the longest resection recorded is a case of Brenner's referred to in Moynihan's "Abdominal Operations," in which 17½ feet were removed, the woman dying 2½ years later of marasmus. Several other cases of resection of more than 14 feet appear to have lived without any signs of malnutrition, whereas other cases in which only 8 or 9 feet have been removed, have suffered from and even died of malnutrition, and it appears that individual peculiarities exist which render any dogmatic statement quite impossible.

### VESICAL PAPILLOMA SIMULATING VESICAL TUBERCULOSIS.

BY ROLF CREASY, M.R.C.S., L.R.C.P. LOND.

I VENTURE to publish the notes of this case as they may prove both interesting and instructive.

**Previous history.**—T. H., 46 years. Primary hæmaturia in December, 1917, frequency of micturition following soon after. Discharged from the Army in March, 1918, for "tuberculosis of testicles and bladder." Attended as an out-patient for 17 months (April, 1918, to August, 1919) at one of our largest London hospitals under treatment for tuberculosis of bladder and testicles. Between May and July he attended at the R.C.S. examinations three times, being shown as a case for diagnosis (in the light of subsequent events one wonders if any luckless candidate was ploughed for not diagnosing T.B. of bladder). Was examined four times to January, 1919, by pensions board and diagnosis confirmed.

**Condition on admission.**—The patient was admitted in August to All Saints' Hospital for Genito-Urinary Diseases, when his condition was as follows: Testicles wasted; nodules felt in both epididymes and thickening of both cords. Prostate normal; vesicles rather thickened. Cystoscopic examination revealed a cherry-sized, innocent papilloma springing from the bladder wall just above the right ureteric orifice. Bladder walls quite healthy, showing no signs of tubercle. Both ureteric orifices normal, with good efflux. Trigone normal. A test dose of old tuberculin, 0.0005 c.cm., gave marked positive reaction, local and general.

#### Points of Interest.

The points of interest in this case are:—

1. The improper assumption of tuberculous bladder because of the tubercle elsewhere. It is surely a grave reflection on the study of urology in our London hospitals that no cystoscopic examination was made in the case of this man complaining for over two years of hæmaturia and frequency of micturition. The case emphasises also the necessity for early cystoscopic examination in all cases of hæmaturia. The cod-liver and malt prescribed in hospital for his condition naturally benefited in no way the papilloma in his bladder.

2. The prompt treatment of his papilloma by Mr. Canny Ryall by diathermy fulguration.

3. The positive reaction to the tuberculin test (which test should without doubt be applied to all cases of suspected tuberculosis of the genito-urinary system), enabling the treatment by tuberculin injections to be at once started.

In regard to the last point, with the assistance of Mr. Ryall and Dr. Camac Wilkinson I am carrying out a series of some 20 cases of genito-urinary tuberculosis treated by tuberculin injections, the result of which I hope to publish in due course.

Grafton-street, W.

### A CASE OF BACILLARY DYSENTERY

IN WHICH FLEXNER-Y WAS RECOVERED FROM THE BLOOD STREAM DURING LIFE.

BY J. S. K. BOYD, M.B., CH.B. GLASG.,

CAPTAIN, R.A.M.C. (T.C.); FORMERLY OFFICER IN CHARGE, BRANCH NO. —, MOB. BACT. LAB., B.S.F.

It is a general experience that dysentery bacilli have been rarely recovered from the blood during life. Glynn and his collaborators<sup>1</sup> (1917) have collected from the literature 15 cases, viz.: *B. dysent.* Shiga, 2; *B. dysent.* Flexner, 1; inagglutinable *B. dysent.* Flexner, 1; and *B. dysent.* Y, 11. In 12 other cases the bacilli were found in the blood after death—viz., Shiga, 6 times; Flexner, 4; Y, 2. Maer<sup>2</sup> (1918) has since recorded the presence of *B. dysent.* Shiga in the blood of a soldier in the East, who subsequently died. Caussade and Marbais<sup>3</sup> (1919) described a remarkable case of acute dysentery with pyrexia, which was fatal in a week. The stools were examined three times, with negative results, for amœbæ and pathogenic bacteria. Typical Shiga bacilli, however, were isolated from the blood post mortem. The patient's blood also gave positive agglutination to Shiga 1-100. The large intestine was inflamed and the epithelium necrosed, but there was no definite ulceration. L. Rosenthal<sup>4</sup> (1903) isolated agglutinable Shiga bacilli from the heart blood and spleen of a male, aged 20, who died after four days' acute dysentery; there was typical dysenteric thickening of the large intestine and the mesenteric glands, which were one and a half times the normal size and contained much blood.

While serving with the Salonika Force in the summer of 1917 I encountered another case, the seventeenth; here Flexner-Y was the organism.

L.-Cpl. K. was admitted to C.C.S. complaining that four days previously he "turned ill with sickness, vomiting, and diarrhoea"; the latter symptoms progressively became worse. On admission his bowels were moving "every few minutes" and he was passing small stools of blood and mucus. He had severe general abdominal pain. He was flushed, but had no typhoid facies. The tongue was dry and heavily furred, the abdomen sunken. No rash was observed, and the spleen was not palpable. The temperature was 100° F. and pulse 98. The patient had not been inoculated against dysentery.

**Stools.**—These presented macroscopically and microscopically the typical appearances of bacillary dysentery—i.e., they were small stools consisting altogether of glairy mucus streaked with blood and contained many leucocytes and a moderate number of red blood corpuscles, desquamated and degenerating epithelial cells. Plated on MacConkey's medium an almost pure culture of an organism with the following cultural characters grew. Glucose—acid, no gas; mannite—acid, no gas; maltose, lactose, and cane—unchanged. The organism was agglutinated to the full titre, 1-1500, by Lister Institute Flexner-Y antiserum.

**Hæmoculture** was performed in the usual way on the day of admission, 2 per cent. bile-salts in distilled water being used. In 36 hours an organism was recovered from this which gave the same cultural and agglutinative characteristics as that isolated from the stool.

Before the special interest of the case was recognised the patient had recovered sufficiently to be evacuated to the base, and was consequently lost sight of.

It will be noted that the organism is of the "Y" type, and that the symptoms show no unusual variation from the ordinary acute dysentery.

I have examined about 12 other apparently similar cases of acute bacillary dysentery in about the same stage of the disease with the same hæmoculture technique, but the results were negative.

## Reviews and Notices of Books.

*Human Infection Carriers.* By CHARLES E. SIMON, B.A., M.D., Professor of Clinical Pathology in the University of Maryland School of Medicine. Philadelphia and New York: Lea and Febiger. Pp. 250.

THE problem of the human carrier of bacterial infection is assuming ever greater importance. Professor Simon regards all such individuals as a menace to society. He "wants to make your flesh creep." He refers to "the hidden foe," and estimates, on figures of doubtful validity, that there must have been at least 2679 carriers of the *B. diphtheriae* in New York in 1915, and that the same city may be assumed to harbour some 25 000 typhoid carriers; though he is led to express some surprise that, in such circumstances, typhoid fever is not much more prevalent than is actually the case. Viewed in this light, as the case for the prosecution, the book makes instructive reading, though it is difficult to withhold some measure of sympathy from the carrier in the dock, and one is left with a feeling that a conviction on all counts would hardly be obtained on the evidence submitted. As a critical survey of the carrier problem the work cannot compare with that of Ledingham and Arkwright published seven years ago, to which, strangely enough, Professor Simon does not once refer. Much recent work in connexion with poliomyelitis, cerebro-spinal fever, and pneumococcal and streptococcal infections is included in the chapters dealing with these subjects. Many of the more important facts which have recently come to light in connexion with the epidemiology of meningococcal infections are, however, omitted or passed lightly over. Certain errors and omissions are probably the result of haste in preparation and will be corrected in a subsequent edition. The most glaring examples occur in the table of fermentation reactions on p. 94.

A strong plea is put forward for the control of convalescents from infectious diseases, based on bacteriological findings, and for the rigid quarantine of all detected carriers, whether convalescent, contact, or non-contact. Where this is obviously impossible the strict limitation of their activities is suggested as the most desirable alternative. Several large assumptions are made: that practically all carriers derive the organisms which they harbour directly or through a series of contacts from a case of the disease in question; that the efficient control of the patient would largely prevent the occurrence of carriers; that our technique is sufficiently accurate to enable us to detect such individuals by a practicable routine; and that a thorough campaign carried out along these lines would eventually eliminate the carriers and hence the diseases which they spread. Almost all these basic assumptions may be, and have been, doubted. In the case of cerebro-spinal fever the rise in the carrier-rate has clearly been shown to precede the epidemic. Once this has started many carriers will be produced by direct or indirect contact with actual cases; yet it may be that the actual case is often the final product of a process in which the passive carrier and the atypical case mark successive stages. The numerous statistical results, which have been obtained as regards repeated examinations of individual carriers over long periods, do not tend to strengthen our confidence in our ability to eliminate these unfortunate persons by practicable measures. The widespread dissemination of the meningococcus among the healthy population, so clearly brought out by the work of Eastwood, Griffith, and others in this country, is hardly compatible with the belief that any scheme of quarantine will avail to rid us of carriers of this organism, and observers of repute have expressed a definite opinion that efforts along these lines are useless in this disease. The book is marred in some respects by being written too exclusively from the point of view of the clinical pathologist, and certain fundamental facts of epidemiology are misstated or ignored. Twice, at least, is the suggestion made that epidemics started by carriers may spread until suitable soil is no longer available. In the sense that an epidemic ceases because all susceptibles have been attacked, this view has been shown by numerous authorities to be untenable. The mischievous activity of certain types of carriers has been demonstrated to the satisfaction of almost all those

who have studied the question, and Professor Simon presents us with several new histories illustrating this, including the latest chapters in the life of the famous "Typhoid Mary."

Among the most interesting features of this work is the appended summary of the State laws and regulations pertaining to infection carriers; and it would be hard to find a better text from which to preach the urgency of further inquiry into the whole matter. Most of the laws and regulations are new. While 16 States, at least, have given no definite rulings on this question, one hopefully includes scarlet fever in a list of diseases in which carriers shall be liable to special control. Illinois strikes a practical note in prohibiting typhoid convalescents from engaging in the preparation or handling of foodstuffs or milk until the excreta are certified to be free from bacilli, and in imposing a fine of not more than \$200 or imprisonment in the county gaol for not more than six months, or both, as a penalty for each offence. The effort to deal with a problem of such real importance along legislative and administrative lines reflects great credit on the activity of the health authorities of the United States, and is full of interest to ourselves in a year marked by the birth of the Ministry of Health. The problem is exactly one where the new Ministry will require sound medical guidance. Are detection and quarantine, involving an enormous amount of bacteriological investigation and the control of many thousands of apparently healthy persons, the only or the best ways to deal with the position? Or is it possible that more will be accomplished by less rigorous methods combined with a determined attempt to lessen overcrowding and to educate the public in the ways of cleaner and more healthy living? How much, again, can we expect from widespread schemes of preventive inoculation, and to how many diseases can this method be usefully extended? If we are to succeed in those plans for the gradual diminution of infective disease, in which our hopes are so largely centred, we must secure the hearty coöperation of the population in general. This might well be lost by restrictive legislation applied without clear proof of its necessity. Unpopularity should never be an excuse for inactivity when the facts are clear, but we should do well to build carefully and on sure foundations.

Professor Simon's book serves to impress upon us that action cannot be indefinitely delayed. If we could learn that the financial outlay involved in a thorough and systematic survey of the whole subject would probably save us from endless mistakes, and some possible disasters in the not far-distant future, we should have gained much.

*Practical Obstetrics.* By E. HASTINGS TWEEDY, F.R.C.P.I., Professor of Obstetrics, Royal College of Surgeons in Ireland, Past Master of the Rotunda Hospital; and G. T. WRENCH, M.D., late Assistant Master. Fourth edition. London: Henry Frowde (Oxford University Press). 1919. Pp. 557. 21s.

THIS edition is particularly interesting, as in the absence of the master, Dr. Henry Jellet, on war service, the governors of the Rotunda Hospital asked three past masters to carry on the work. Dr. Hastings Tweedy therefore has had exceptional opportunities of renewing his acquaintance with the clinical teaching of that institution which is embodied in the present volume. The demand for a fourth edition in so short a space of time shows the practical success of the work, which is founded upon the experience gained in what is, taken all round, the best lying-in hospital in the United Kingdom. We may not all of us agree with some of the details of the teaching of the Dublin school, but that the "Rotunda" opinion upon any matter in the science and art of obstetrics must be seriously accepted no one could be found to deny.

In view of the interest the subject is exciting at present the results of the observations of Dr. J. R. Freeland and Dr. B. Solomons on twilight sleep are important. Their report is, on the whole, in favour of the method, but it must be noted that they gave, as a rule, relatively small doses and only 10 out of their 100 cases appear to have exhibited complete analgesia. The authors believe that the results obtained by scopolamine-morphia injections demonstrate that so-called secondary uterine inertia is in reality not due to a "tired-out uterus" but to a "tired-out woman," and that the

appearance of strong labour pains in the early stages of labour is due to an hysterical condition of exaggeration and alarm in a hypersensitive woman. The very constant effect of twilight sleep has in producing secondary uterine inertia must, however, be borne in mind, and we regard the teaching that there are two conditions of primary and secondary uterine inertia and a third one of obstructed labour to be the more correct.

The section dealing with the treatment of eclampsia is a very good one, and the fact that in an appendix the authors have reprinted a paper read by one of them before the International Medical Congress, 1911, and also a paper by Stroganoff, gives the reader additional information in regard to the methods described in the text, methods which certainly give extremely good results. The two-bladed cephalotribe is at the present time old-fashioned, and, we imagine, seldom used. If a practitioner attempted to use the instrument according to the description given by the authors he would certainly fail in a difficult case—that is, if we are right in assuming that Braxton Hicks's instrument is referred to. The authors still favour plugging in the treatment of rupture of the uterus, and quote six cases successfully treated by this method. It is a pity they do not state whether these were cases of complete or incomplete rupture. But in spite of these slight differences of opinion between us and the authors, we regard their book as a very good one and one which can be most highly recommended both to students and practitioners as thoroughly sound in its teaching.

*Veneral Diseases: a Practical Handbook for Students.* By C. H. BROWNING, M.D., D.P.H., and DAVID WATSON, M.B., C.M. London: Henry Frowde and Hodder and Stoughton. 1919. Pp. 336. 16s.

IN order that students should benefit to the greatest advantage from any treatise three conditions must be fulfilled. The presentation of the subject must be systematic, clearness and brevity must go hand in hand, and the information afforded should be stimulating.

This volume is divided into two parts, the first treating of syphilis and the second of gonorrhoea. In Section I. (Syphilis) the foregoing conditions are, on the whole, admirably satisfied. From the student's point of view the pathological teaching is extremely good. We can find little which calls for adverse criticism, much that deserves eulogy. The illustrations are on the whole good, but we think that the plates (2, 3, and 4) illustrative of different chancres might be much more definite. More space might have been allotted to the differential diagnosis of penile and other chancres.

It is not necessary or desirable for anyone to attempt to carry out the Wassermann test unless he is justified by long experience in doing so. Every practitioner, however, should understand its rationale, and therefore we are sorry to find that the explanation of this reaction is not as clear as it might be. Now that the importance of the pre-natal treatment of syphilis is recognised, it is to be regretted that no more than 2½ lines are devoted to this subject.

It would have been more satisfactory if the authors had given their readers more definite ideas as to the comparative value of the various substances which are now being used for the administration of intravenous injections. We consider that the paragraph devoted to the "contra-indications" to the administration of salvarsan should at least give some definite information for the benefit of students as to the course to be adopted with a patient who is suffering from chronic Bright's disease, acute nephritis, or aortic disease. The statement that "there are no absolute contra-indications to the administration of the drug" is one that will not commend itself generally to syphilologists. If it is necessary to devote half a page to the illustration of an apparatus for giving intravenous injection by pressure, it is desirable to afford some explanation of its methods of action. Lastly, after calling attention to the emergencies contingent upon the administration of salvarsan treatment, it is advisable to give the student information as to how to combat the same. We are purposely pointing out what we think to be weak spots in a valuable section of the treatise.

But while we believe that the first part of this book is, as a whole, admirably suited to subserve the purpose of its existence as "a practical handbook for students," the same can hardly be said of the second section on

"Gonorrhoea." It is not systematic, and therefore it is not clear. We are certain that the student knowing nothing of his subject who comes to this volume for instruction will leave it in a mentally nebulous condition. The aim of a work of this nature should be to instruct a student how to examine and treat a case of gonorrhoea in a methodical fashion. In this respect the authors have failed, and, further, their teaching is not always in agreement with the best views. In regard to the treatment of acute anterior urethritis the authors warn the students with respect to injections as given by a syringe. "No force must be used, otherwise a minute quantity of gonococcus-laden pus may be forced into the posterior urethra and an acute posterior urethritis incited. This is an accident which frequently happens in cases treated by this method." On pages 190-191 the authors advise what they term "urethro-vesical lavation" (generally termed posterior irrigation). They advise that the reservoir containing the antiseptic fluid should be placed at a height of 4½ feet above the level of the patient's pelvis. We feel assured that the danger which they aim at preventing when using the syringe will be lavishly present if the above method of "lavation" be used in a case of anterior urethritis. Again, in dealing with the subject of chronic gonococcal urethritis the authors fail to emphasise sufficiently the value of digital examination of the prostate and of the vesicles. This we regard as a serious omission; in fact, we consider it most necessary to impress upon students the need which exists for the valuable information which is to be obtained from the constant examination of prostate and vesicles. For there is no doubt that the rectal is the high road which leads to success in both the diagnosis and treatment of chronic posterior urethritis.

The consideration of the subject of strictures, their diagnosis and treatment, is inadequate, and when it is considered what can be effected by careful dilatation and the resultant avoidance of urethrotomy the omission is a serious one. Insufficient attention is given to the technique involved in urethroscopic examination. We regret, also, that we are unable to find any reference to the necessity of making a systematic examination of every patient before he is discharged from treatment. The authors suggest that "any persons who have previously suffered from gonorrhoea should submit to an expert medical examination before marriage." This is not enough. Every patient who has been under treatment for gonorrhoea should be systematically examined before he is discharged, whether married, about to be married, or without any idea of marriage. From a sociological point of view the man who has no idea of marriage is likely to prove the most dangerous to the community if he is discharged from treatment without a thorough examination.

We are sure that the authors can make a valuable treatise out of their work if they will boldly throw over altogether the teaching of the schools where it conflicts with recent clinical experience, and will bear in mind that the present-day student must be equipped on every hand for a medico-social conflict.

*Through a Tent Door.* By ROBERT WILLIAM MACKENNA. M.D., R.A.M.C. London: John Murray. 1919. Pp. 310. 8s. net.

THIS book of war essays has none of the robustness and rollicking humour of others of its kind, though it is possibly none the worse for that. Incidents of the war as seen from a field hospital form the basis of the book, but one feels that the author would have been just as happy had his vantage point been an English provincial hospital, for his comments on life rather than on action. He is interested in books, religion, and human nature—in fact, in things in general; and it is merely an accident that he happens to have thought and written in Flanders. Dr. Mackenna has a pleasant, gentle style, somewhat reminiscent of Elia, and on the whole his work reaches a high level. Were we called upon to select any one essay for special praise it would be the one entitled "Through a Tent Door," but many others are almost equally successful. "The Visitant," a work of pure imagination, pleased us least; and "Margarine and Café-au-lait," a desultory discourse on books, might well have been omitted; the kind of thing has been done, and done better, elsewhere. Dr. Mackenna's public may not be large, but it will be appreciative, for his work is thoughtful and sincere.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 13, 1919.

## The Eradication of Epidemic Diseases.

CAN the great epidemics of disease which from time to time sweep over the whole or a great part of the earth's surface be prevented by human effort? Will it ever prove possible to trace them to their place of origin, and by appropriate measures applied there destroy the cause of each disease at its very source? In the case of a large number of infectious diseases human effort can, and does to a great extent, control the spread of an infection once introduced, and limit its disastrous effects on the community. But the aim of the epidemiologist and public health administrator is something higher than this. To them, even more than to the clinician, prevention is infinitely to be preferred to cure, for while he deals with single lives they are dealing with lives in countless numbers. When the recent truly terrible epidemic of influenza (we use the words deliberately, for the deaths caused by that epidemic outnumbered immeasurably those caused by four and a half years of the greatest war in history) swept over the world, how many—or how few—persons were saved from its attacks by individual or by communal measures of precaution? The medical profession cannot claim that the course of the epidemic was seriously affected, still less stayed, by any such measures. Had it proved possible to detect from the outset the place of origin of the disease and to destroy the infection then and there, or at least to prevent its spread beyond local limits, the millions of lives thus sacrificed might have been saved; one more—and perhaps the greatest of all—would have been added to the list of triumphs of preventive medicine; and the very course of history itself might have been changed. And if this is true of influenza, it is no less true of other and allied epidemic diseases.

We have been led along this line of thought by the instructive presidential address delivered by Dr. SIMON FLEXNER before the recent Congress of American Physicians and Surgeons. The address covered much ground, and we only here refer to one or two of its salient points, as they appear in the abstract printed in our issue of last week. As Dr. FLEXNER points out, in the case of one disease at least, the aim we have tried to formulate above has been actually attained. "We have," he says, "a splendid example of eradication of disease in yellow fever. We did not wait for the disease to become epidemic; it was destroyed in its endemic home." But in the case of influenza the problem to be solved is more complex than in that of yellow fever, and more complex perhaps than Dr. FLEXNER's remarks (of necessity much concentrated in our abstract) seem to imply. "In the history of epidemics," he says, "influenza took its origin in a region somewhere near the Russian border of Turkestan, spreading along the trade routes as rapidly as transportation moved. . . . The endemic focus of influenza is somewhere on the Eastern border of Russia." Consequently he holds that "it is not too much for a reconstructive

medical profession to conceive the clearing up a region which by its inaccessibility and its neglect has every 25 or 30 years originated waves of disease spreading over the globe." We should share this hope more willingly were we convinced of the correctness of the geographical premise. In the great pandemic of 1889 and subsequent years there was strong evidence to show that the outbreak did in truth take its origin on the borders of European and Asiatic Russia. The evidence was set forth in two articles<sup>1</sup> published in THE LANCET by Dr. F. G. CLEMON in 1894, and was based on original and unpublished reports made by Russian doctors in the regions in question to the Medical Department of the Russian Ministry of the Interior at the time of the epidemic. But that evidence was restricted to one particular outbreak of the disease, and we are not aware that it has ever been claimed, or that the historical facts would lend any support to such a claim, that influenza epidemics always or even frequently arise in the regions indicated. The so-called "Spanish influenza" of 1918-19 arose we know not where. The records of its course, owing to the state of the world at the time, were far more imperfect than those of the 1889 pandemic; and, so far as they are available, they do not seem to show the same clear progress from one well-defined centre to the rest of the globe. In this respect influenza must always, save perhaps on rare occasions, offer great difficulties to those who would aim at destroying it at its source. But the aim need not for that reason be lost sight of. The interests at stake and the rewards of success in preventing even one single pandemic, such as that of 1889 or 1918, are on too colossal a scale for a policy of despair; and we fully share the hope that, when order once more reigns in Russia, a careful watch may be kept on the regions which gave birth to at least one great epidemic of influenza, and may yet give rise to another.

But while a massed attack on an endemic focus seems as yet too sanguine a prospect where influenza is in question, the conditions surrounding the origin of the great cholera epidemics offer more hope for the attainment of the aim. The endemic home of cholera is universally believed to lie in Lower Bengal—in the Sundarbans and the delta of the Ganges. The problem of the eradication of this disease, therefore, is not complicated by uncertainty as to its place of origin. The real difficulties arise here when the practical measures necessary for such eradication come to be considered. The large size of the area in question, the engineering difficulties, and the cost, with no direct financial profit, of draining and "sanitating" this vast region all stand in the way of a radical solution of the cholera problem. But these are not in truth insuperable difficulties. In a world awake to the blessings of health can any cost be deemed too great or any obstacles be thought insuperable where the saving of millions of human lives and the prevention of incalculable suffering will be the rewards of success? Each of the great epidemic diseases presents its own special problems, and preventive medicine can already claim a wonderful series of triumphs in discovering the causes of most of these diseases and pointing the way to their control. It may no less proudly claim to have opened the eyes of modern statesmen and administrators to the overwhelming importance to the

<sup>1</sup> Recent Pandemic of Influenza, its Place of Origin and Mode of Spread, THE LANCET, Jan. 20th and Feb. 10th, 1894.

State and the people of dealing seriously with the problems of disease prevention. To-day large, costly, and far-seeing measures with this object occupy a place in practical politics. But we like to picture a world where the prevention and eradication of all diseases that can be prevented or eradicated should be the aim—even the *first* aim—of national and international policy and effort; where measures having as their object the saving of millions of human lives would be thought as worthy of a great statesman's energies and of the interest of the public as Free Trade, bimetallism, and the nationalisation of railways. It may—and, indeed, we are not optimistic enough to doubt that it must—take many long years to reach this ideal. But in the meantime much may, and should, be done; and we hold that it should prove quite feasible to trace some, if not all, of the great pandemic diseases to their source and to make a serious effort to stifle them in their cradle. We do not hide from ourselves the vastness of the task or the practical difficulties to be overcome, but modern science exults in difficulties. When the smoke and noise of war have cleared away, and the nations are really at peace again, the statesmen of the world could find no higher or more stimulating aim for their energies than the cleansing of epidemic breeding grounds.

### The Teaching of Obstetrics in London.

No one who has read the report of the Committee of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, appointed to consider this subject, can fail to agree with their conclusions that the present methods of teaching midwifery are very defective. There has been little alteration in these methods for a long time past, and while it is true that the establishment of midwifery wards of recent years in certain of the hospitals has done something towards reform, the main and gravest defect still remains. We refer to the fact, strongly emphasised by the Committee, that the student learning clinical midwifery is completely out of touch with his senior teachers, as he does not see them actually engaged in the work he is trying to learn and seldom has the advantage of their supervision and guidance. This is certainly true of those hospitals, the great majority in London, which have no midwifery ward, and even in those which have it is true to a very large extent. It is generally impossible for the senior members of the staff to be present at any normal labours, and it is no exaggeration to say that in most hospitals they are not there even when a case of abnormal labour is being conducted, and the most the student can expect to see is the performance of the Cæsarean section by one of the visiting staff, a class of case he will seldom meet with and an operation he will probably never attempt. The result of this is that while in medicine and surgery the student has the great advantage of receiving most of his clinical teaching from the visiting physicians or surgeons, in midwifery, just as important a subject, the teaching is mainly in the hands of junior residents or registrars.

This being the case, it is little wonder that the reputation of the London School of Obstetric Medicine is but a poor one, and that research in the subject is practically non-existent. It is high time that some change was made and that the

whole matter was put upon a more satisfactory basis. Not only is the clinical teaching of midwifery in London very deficient, but the small number of beds available for lying-in cases is almost scandalous. In these days the medical student no longer should be dependent upon attendance in the extern maternity department for his experience in midwifery practice. In the unsuitable surroundings that obtain in the homes of the poor it is quite impossible for antiseptic or aseptic methods of conducting a confinement to be efficiently carried out, and if they cannot be properly practised they cannot be properly taught, as they should be by example and not merely by precept. One of the pressing needs of London, and, indeed, of every other town in the country, is a more adequate provision of lying-in beds. It should be possible for every woman who desires to do so to be admitted to a properly equipped lying-in hospital, and it should be just as great a scandal to conduct a difficult case of midwifery, possibly necessitating an operation, in the utterly unsuitable surroundings of a tenement house as it would be to carry out even a simple surgical operation amid such surroundings. And yet this is happening every day in the week and almost every hour in the day. In the ratio that exists between the number of beds available and the number of beds required for lying-in cases, we imagine that London is in a worse position than any other large city in the world. It is to be hoped that the new Ministry of Health will take this matter in hand and will insist that the provision of lying-in beds in the large hospitals with medical schools should be such as to render it possible to admit other cases than merely those which are sent in from the maternity, district or by medical practitioners because they require operative interference. The fact that a woman who has to undergo an obstetric operation frequently runs a greater risk than one who has to undergo an ordinary major operation of surgery should be made quite clear to the public, and it is not just or fair that in these circumstances she should be terribly penalised because sufficient accommodation is not to be found in the large voluntary hospitals. The fact that neither the majority of the medical staffs nor the managing committees of many hospitals appear to recognise the necessity for such a provision is becoming a strong argument for placing the hospitals under State control.

But when the beds needed have been provided they will be useless from the student's point of view unless a very radical change is brought about in the present methods of teaching. The crux of the whole question lies in the provision of some means whereby the student can receive his teaching in theoretical and practical midwifery from teachers of a class comparable to those who are engaged in teaching him medicine and surgery. As we have pointed out, at present this is only true as regards systematic instruction in midwifery, the practical teaching being mainly in the hands of junior teachers occasionally but seldom above the rank of a registrar. In the near future, perhaps, several of the medical schools in London will have whole-time properly paid teachers in medicine and surgery, and no one who has given any attention to the needs of medical education can doubt that this step will tend not only to advance and improve the theoretical and clinical teaching, but that it will tend also greatly to the advancement of

research in these two subjects. An appointment in obstetrics on these lines—namely, a whole-time properly paid teacher provided with paid assistants and with adequate laboratory accommodation for the carrying out of research—is urgently needed, and is one of the chief recommendations of the Committee whose report we are considering. Whether such a teacher should be the head of a separate institution on the lines of the Rotunda Hospital in Dublin, or whether he should be closely associated with one of the existing medical schools and take charge of a greatly enlarged obstetrical and gynaecological department in the associated hospital is largely a matter of convenience and detail; the principle remains the same in either case. Until an appointment of this kind is made by which the student will be taught his theoretical midwifery and be able to see clinical midwifery practised and obstetrical operations carried out as they should be carried out, in suitable surroundings by a master of the art, the teaching of midwifery will never make any appreciable progress in London, and the reproach that research in this subject in London is a negligible quantity will never be overcome. We have said little about the teaching of the London student in gynaecology, because on the whole it is satisfactory, the same difficulties do not surround it, and no modifications are really required, but the two subjects cannot, and should not, be divorced. They should be taught together in a single institute, and under the same roof should be located a corresponding maternity and child-welfare centre.

### Mind and Medicine.

THE truism that history repeats itself is suggested by the reading of a lecture with this title delivered in the John Rylands Library by Dr. W. H. R. RIVERS, Prælector in Natural Sciences at St. John's College, Cambridge. Continual progress and fresh scientific discoveries notwithstanding, an impartial scanning of the phases or trends of medicine at various epochs in world history points to the conclusion that the human mind in its relation to the practice of medicine moves through cycles in which time is measured not by years but by centuries. Primitive associations of medicine with religion and with magic seem in the fullness of time to be replaced by modern associations not widely differing in essence. Subsequent search for a material basis for disease in a humoral theory is paralleled by a not much more scientific conception of the interrelation of the endocrine glands and their bearing on many morbid states. To the student of medicine the succession of animism by materialism, and of the latter by deeper appreciation of the mental factor in disease does not, however, represent the historical facts other than superficially. At no time has either the mental or the material factor been predominant to the complete exclusion of the other; as long as a dual conception of man's being has existed, so long has medical opinion oscillated between one and other aspect of it, and so will it continue to oscillate. A system of healing styled "New Thought" is in reality very old thought; while the organisms of the germ theory are the counterpart of the worms and snakes of savage medicine.

What is new is the determination of the precise scope of the psychological factor in disease, and the laying down of the principles of psychotherapy. For the time, we may say, the growing point of the study of nervous disease is in the direction of

applied psychotherapy, thanks to the immense impetus afforded by the silent appeal of the phalanx of sufferers from war neuroses and psychoneuroses. Behind the therapy looms large the desire to probe further into the why and the wherefore, hence the renewed investigation of psychical theories of disease, and, as Dr. RIVERS justly concludes, the willingness of the great majority of students to consider the position, and to accept, in part at least, the doctrine of pioneers such as FREUD. Appreciation of the importance of psycho-analysis as a means of discovering what lies behind the external phenomena of functional nervous disease implies no acceptance of the Freudian attribution of all neurosis to disordered sexuality; for that matter, there is no finality of interpretation of the symbols, which, in Freudian doctrine, constitute a large proportion of the stuff of the mind, still less of the motives laid bare by such technique. Thus should a hidden spring of action be shown to be linked with some "woman in the case" it would not thereby necessarily bear only a sexual interpretation. In one of his University sermons the late Principal EDWARD CAIRD laid stress on the love of knowledge for its own sake as one of the potent dynamic forces stirring the mind of man to action, and should this be given fuller effect by one in his love for his partner, its tingeing with an added colour does not alter its essentially non-sexual nature.

As the working man insists on his war bonus being permanently incorporated in his wages, so the advances recently made in the understanding of the unseen trends of the human mind will be permanently embodied in medical doctrine. There can be no going back to the barren psychology of the schools. We have learned too much of the significance of the affective or emotional aspects of functional nervous disease to rest content with what is little less than therapeutical "bluff." The casual patient, it must frankly be admitted, knows not merely much about venereal disease that was hidden from his father; he has heard of blood-tests, and demands treatment by injections; he also knows more than some physicians may suspect of how "nerves" should be treated and will not submit to be put off by an airy reassurance. If the modern hospital is to earn or enhance a reputation for healing the sick it must take cognisance of all the ills to which flesh is heir and organise a neurological department for the benefit, among others, of the sufferer from functional nervous disease, presided over by, or including on its staff, someone trained in the recent acquisitions of knowledge and convinced that psychological disorders deserve psychological treatment. This investigation of the underworld of conflicting impulses, desires, and instincts must lead also to the medical man's playing a greater part in the solution of the problems of criminology. The criminal deserves psychological study at least as much as, if not more than, legal. Social and political problems, too, are in their turn based on deeper problems of the trends of the social mind which provide a fit subject for patient research. We should not claim mere psychological analysis to be a panacea for the disorders of the body politic, but we are frequently reminded by intelligent publicists of the real roots of social unrest in feelings and impulses that are essentially only half-expressed, and therefore potential mischief-makers unless dealt with as the psychologist deals with the impulses of the individual. In all this we see a ripe field for systematic investigation by competent workers.

"Ne quid nlmis."

### OFFICERS FOR THE R.A.M.C.: THE NEW CONTRACT.

IN the recent Students' Number of THE LANCET we regretted the inability to publish the rates of pay that would be contained in the new contract which the Army Medical Service was prepared to offer to medical practitioners, though we were able to announce that these terms would be of a very advantageous sort. This week the new contract has been made public, and the conditions under which the War Office is prepared to accept the services of medical practitioners, including those who have been demobilised, will be found set out on page 503 of this issue. The contract, it will be seen, is in many ways a great improvement on the old one. The pay is increased for lieutenants and captains, so that the pecuniary start which the young man receives by qualifying for a commission in the R.A.M.C. is now a distinctly good one. There are allowances for foreign service, and specialist or charge pay is available in certain conditions. As directorates in pathology and in hygiene have now been created within the Army Medical Department, specially selected men can rise through all the ranks of the Army to Major-General on the strength of their scientific work, and we have before now insisted on the attractive nature of the outlook which is thus provided for the scientifically minded man. Applications for commissions should be addressed to the Secretary, War Office, Cornwall House, Stamford-street, London, S.E.1. The full regulations for admission and form of application will be found in the Students' Number of THE LANCET, August 30th, 1919, p. 397.

### THE MEDICAL ASPECTS OF STATE SCIENTIFIC AND INDUSTRIAL RESEARCH.

THE report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1918-19, issued last week, claims for the work of the department over this period a steady growth both in usefulness and in amount. This is the fourth annual report of their proceedings, and a review of the detailed work of the Advisory Council, which forms the executive of the department, fully justifies this claim. The personnel of this Council includes authorities of the highest standing on the manifold subjects investigated, whilst the assessors to the Council, responsible for the departmental work and organisation of research, are all experts in the various Government Departments which they officially represent. The outcome is an official compilation of progressive work in research and industry, the results of which deeply concern the future industrial welfare of the nation. The solvency of the nation may well, indeed, depend upon the earnestness with which the lessons conveyed by this work are absorbed.

Scientific and industrial research are wide terms of reference, and the scope of inquiry includes, as will be anticipated, medical matters of insistent interest. Such, for example, are mine rescue apparatus, the preparation and preservation of foods, cold storage and its effect on meat, oxygen research, industrial fatigue, the rendering

of "power alcohol" undrinkable, and the patent laws, in so far as they affect discoveries which concern the health and life of the people. It is interesting to learn that the Advisory Council recognise the strong professional tradition of the medical profession in this country in regard to the patenting of inventions of genuine value for the preservation of health or of life, and the Council have provisionally decided that applications for patents within this category should be refused. It is admitted, however, that the whole question needs careful watching and discussion by those best able to form a judgment. There seems to be a suggestion that the State should take over such inventions and reward the inventor on a scale which would compare reasonably with that compensation which he would gain by patent protection. The scale of remuneration by the State in such a case would form an interesting contrast with the enormous profits made from the sale of secret remedies based on no discovery at all; these profits, in the main, are mercenary exploitations purely and simply. Such preparations are in no sense patented medicines, for in that case they could not be secret remedies, as a patent implies the publication and protection of their composition. The Government compels the use of a stamp in the sale transactions, which means no more than the stamp on a receipted bill exceeding £2 in value. In other words, the stamp is a duty and in no sense a guarantee that the preparation is an approved therapeutic agent. This official procedure, however, no doubt helps materially the sale of many nostrums. We hope the Government will introduce a much-needed reform on the lines suggested in the admirable report of the Select Committee of Patent Medicines, which was ordered by the House of Commons to be printed on the very day war broke out. Since then nothing has been done. The Committee of the Privy Council for Scientific and Industrial Research might note these things. It is a body with great prestige, and its constitution, which has recently come under acute criticism, may put it out of sympathy with pure research, but should enable it to act forcibly in the cause of practical reforms.

### A CASE OF LETHARGY.

THE case related by Dr. Grace H. Giffen Dundas in our issue of last week presents features of interest and rarity. The illness from which the patient, a young woman, suffered had an acute onset, with rise of temperature, increase of pulse and respiration, headache, sweating, and other signs pointing clearly to a toxi-infective condition. These general symptoms were coupled with others of localising significance, including paresis or paralysis of various motor cranial nerves (though Dr. Dundas excludes the third nerves she specially mentions sluggish pupil reactions and partial double ptosis), resulting in, among other things, a mask-like facies and inability to depress the lower jaw. The arms and legs were rigid and motionless, and there was a double extensor response. Bladder and rectal control were greatly impaired. The patient slept deeply most of the time. There can be little doubt that the correct neurological diagnosis is encephalitis lethargica, which is usually characterised by general symptoms of cerebral toxæmia and localising symptoms pointing to mesencephalic involvement, precisely as in this case. The lower motor cranial nerves were rather more

involved than the upper, as occasionally occurs; the limb paralysis is an index of the severity of the attack, but does not necessarily signify a structural change in the cortico-spinal paths or centres; an extensor response may occur where no change in structure is demonstrable. An examination of the spinal fluid by lumbar puncture would doubtless have been of considerable help in diagnosis if only for the exclusion of other conditions with which the case might be confused. It is not quite clear whether the patient showed a true catatonia or not—a common symptom in lethargic encephalitis; Dr. Dundas speaks of the cataleptic-like condition, but does not state whether, for instance, the limbs remained in any position in which they were put; as there was no voluntary movement the test would have had to be made by lifting the arms passively off the bed. One of the distinctly unusual features is the loss of the sense of position in the limbs; the fact that the patient did not know her limbs were being manipulated may also be taken to indicate cutaneous loss of sensibility, and there is no a priori reason why such might not occur in encephalitis. On the other hand, however, she was aware of her incontinence and knew when the catheter was being passed, so that it is possible the loss of position and direction was an index of the cerebral apathy. To this suggestion it might with justice be replied that were such the case she would probably also have been indifferent to her incontinence. Of considerable scientific interest are the peculiar hallucinations, as exemplified by "her eyes up at the roots of her hair and her teeth several inches in front of her mouth." Some alienists have insisted that hallucinations of the muscular sense in the insane are of unfavourable prognostic import as compared with those of other senses (sight, hearing), and indicative of a greater degree of cortical defect. Be this as it may, Dr. Dundas's patient made a perfect and on the whole rather quick recovery considering the acuteness of the illness. One might hazard a conjecture that the ignorance of the position of the limbs and the erroneous references in respect of other parts of the body (eyes, teeth) were both the expression of a disturbance of the "sense of attitude," which is something more than mere impairment of sense of position.

#### EROSION OF THE GREAT VESSELS OF THE NECK IN SCARLATINAL ABSCESS.

CERVICAL adenitis with abscess formation is a common complication of scarlet fever. A very rare consequence is erosion of one of the great vessels of the neck, with serious and even fatal hæmorrhage. In the Johns Hopkins Hospital Bulletin for August Mr. T. M. Rivers has reported the following case. On Dec. 1st, 1916, a girl, aged 5½ years, vomited and had slight fever. Two days later a practitioner was called in, found a small membrane on the right tonsil, and administered 15,000 units of diphtheria antitoxin. About Dec. 5th the cervical glands began to swell, she became stuporous, and did not pass urine for 56 hours; then a small amount of urine containing much albumin was passed. In the third week a diffuse maculo-papular rash appeared and she was admitted to hospital three days later. The temperature was 99°F. and the pulse 110. She was drowsy and emaciated. The tongue was heavily coated and the breath foul. Part of the tonsil, soft palate, and posterior pillar on the right side had sloughed, leaving a ragged hole lined with greenish-

white pus. The cervical glands were enlarged. There was a fluctuating mass of the size of a lemon, deeply situated, below the right angle of the jaw. The liver extended two fingers' breadth below the ribs. Over the body was worm-eaten desquamation. The palms and soles were very dry and later desquamated in a way typical of scarlet fever. A throat culture was negative for diphtheria bacilli, but showed long chains of streptococci. The urine contained 3 g. per litre of albumin, hyaline and granular casts, pus cells, red blood corpuscles, and epithelial cells. The abscess was punctured and 2 oz. of pus escaped, from which a hæmolytic streptococcus was grown. She seemed to be doing well until 11 P.M. on Dec. 26th, when she was found in a pool of blood, exsanguine, pulseless, and gasping for breath. The bleeding had stopped and the wound was not disturbed. A subcutaneous injection of 300 c.cm. of saline solution was given and an intravenous injection of 225 c.cm. of citrated blood obtained from the mother. There was another hæmorrhage of about 2 oz. at 7 A.M. and at 11 A.M. Blood began to spurt from the wound at 1 P.M. Dr. Dandy, the resident surgeon, enlarged the incision into the abscess and found erosion of the lingual and external carotid arteries and internal jugular vein, the hæmorrhage coming from all three sources. The common carotid was ligatured and the bleeding from the jugular was controlled by packing. The child was greatly exsanguinated, and was given 150 c.cm. of citrated blood which had been kept on ice since the transfusion the previous night. She rallied immediately, but the pulse remained irregular for weeks. On the 28th the hæmoglobin was 40 per cent. On the 29th she received 200 c.cm. of citrated blood. On the 30th her hæmoglobin was 58 per cent. Both ear drums were punctured, releasing pus. On Jan. 1st there was another large hæmorrhage. Evidently the carotid ligature had sloughed. The bleeding was controlled by pressure and 150 c.cm. of citrated blood were given. General œdema, insensibility to pain, waxy flexibility, exaggerated reflexes, double ankle clonus, and loss of memory for recent events developed. She gradually improved and the wound healed slowly under Dakin's solution. Recovery ensued. Mr. Rivers could find recorded only about 50 cases of erosion of the great vessels of the neck after scarlet fever. Curiously the great majority are old, only one being reported subsequently to 1885. Two were recorded in our columns in 1870<sup>1</sup>—one by Lovegrove, in which the patient bled to death in a short time through ear, nose, and mouth, and the other by Hymes, in which the patient bled to death through ear and mouth. Is the absence of cases in recent years due to diminished virulence of the disease? Veins and arteries have been involved about equally. The bleeding may come from an opened abscess, from the ear, or through the mouth and nose. Most cases have been fatal.

#### MEDICAL EDUCATION IN THE UNITED STATES.

THE annual educational number of the *Journal of the American Medical Association* (issue of August 16th) contains an interesting summary of the facilities for medical study offered in the United States of America for the year ending June 30th, 1919. It is well known that the United States had at one time more medical schools than the rest of the world put together, the supply far exceeding the needs of the country. Reduction in

<sup>1</sup> THE LANCET, 1870, i., 729, and ii., 431.

the number to one-half has been one of the principal signs of progress in the last 15 years, and the reduction is still going on. Of the 13,052 students studying medicine (578 less than in 1918) the very large majority—94 per cent.—were doing so in “non-sectarian” colleges. Homœopathic colleges scored an attendance of 397, “eclectic” colleges of 86, while 310 students were obtaining their instruction at a group of colleges, 2 of them “semi-osteopathic” and outlawed in their own State of Missouri, the third “eclectic” and not subject to a set curriculum. It is evident that in the United States the tendency is now prevailing towards a standardisation of medical training on broad, orthodox lines. 2656 students graduated in medicine during the year, 44 per cent. of them being already graduates of colleges of liberal arts, witness of a growing appreciation of the value to medical practice of a sound preliminary training. Compared with conditions ruling here, it is surprising to note what a small proportion of their cost of training is paid by medical students themselves. Financial reports from 82 schools show an average annual expenditure per student of \$419, of which the student only pays \$150. A State-controlled medical service should not be difficult to introduce in a country in which the State already contributes, directly or by endowment, 60 per cent. or more of the cost of medical training. In regard to the character of the training, the most important change noted is the gradual replacement of lectures and lecture clinics by bedside training in small group clinics. Thus in all important respects the medical curriculum this side and that side of the Atlantic is converging towards a common objective.

#### PELLAGRA AMONG TURKISH PRISONERS OF WAR IN EGYPT.

A VALUABLE contribution to the literature of pellagra has recently been published at Alexandria by the military authorities, dealing with the occurrence of the disease among captured Ottoman troops. A prevalence of pellagra having been reported among the Turkish prisoners of war interned at Kantara, in Lower Egypt, the D.M.S. Egyptian Expeditionary Force appointed a committee to investigate whether the disease in question was in reality true pellagra, and, if so, whether the prisoners of war were generally infected before or after their capture; whether the disease was increasing; and, if so, was it spreading by infection from case to case or by infection due to location or local conditions; or whether, on the other hand, it was due to some defect in diet or to other general conditions. Further, the committee was to investigate the etiology of the malady in its relation to bacteria, protozoa, blood conditions, pathology, and food. The committee consisted of Colonel F. D. Boyd, C.M.G., A.M.S., consulting physician to the E.E.F., and Lieutenant-Colonel P. S. Lelean, C.B., R.A.M.C., assistant professor of hygiene, R.A.M. College, along with six collaborators, each an expert, respectively, in pathology, bromatology, protozoology, biochemistry, hæmatology, and bacteriology. The inquiry was begun on Oct. 7th, and the report<sup>1</sup> is dated Dec. 31st, 1918. The conclusions of the committee of inquiry may be summed up as follows: The disease was true pellagra and the patients were generally

pellagrous before capture. The great majority of the cases that were systematically questioned stated that they had similar symptoms before capture, while amongst those examined shortly after they were made prisoners many were found suffering from the fully developed disease. For example, in one batch of 1300 prisoners seen on their arrival direct from the front, 18 per cent. had the malady fully developed. There was no evidence of case-to-case infection, and none pointing to location or local conditions having had anything to do with the causation or spread of the disease. The camps at Kantara left little to be desired as regards their situation and hygienic condition. As regards diet, judged by existing standards, the food issued to both non-labour and labour prisoners provided an ample margin over the requirements of healthy men and gave a suitable balance of proximate food principles. Any increase in the disease has not been due to other general conditions than those unavoidable for prisoners in monotonous confinement in an alien, hot, and arid country, with no stimulus to check the inevitable decline in their physiological resistance. Pellagra as a primary or immediate cause of death played an insignificant part in the series of cases that were examined. As a contributory cause its influence was shared by other debilitating diseases, of which chronic dysentery was the worst. After thorough investigation by the various experts, no evidence was found as to the ætiological relationship of the disease to bacteria, protozoa, or to blood conditions. With regard to food, the committee found so constant an association between the biological protein value of diet and the occurrence of pellagra that they considered that the lack of sufficient biological value of protein stands in ætiological relationship to pellagra, certainly as an exciting factor, and possibly as the determining factor. The report states that the deficiency in biological value of protein may be: first, absolute, as determined by the standard for normal persons, or, secondly, relative, as determined by individualistic correlation between food assimilation and energy expenditure, and thus modified by ill-health and idiosyncrasy. A large proportion of the cases showed helminthic and flagellate infections of the intestines. These cannot be regarded as causal factors, but merely contributory to digestive disturbance and malnutrition. Pellagra produces loss of resistance to the invasion of bacterial and protozoal disease, and this is, therefore, a contributory factor to a high rate of mortality. The recommendations made by the committee were:—1. In view of the pellagra admission rates having remained approximately constant in non-labour camps during the last two months, and having diminished so markedly in labour camps in the present month (December), it is considered that the full authorised diets are adequate, and that it is not necessary at present to introduce any cardinal change. 2. Full variety should be given under the alternatives of the existing ration scales, and close supervision should be exercised over preparation and cooking of food, with special regard to pulses in both respects. 3. Any increase in pellagra should be met by an increase in animal protein; the occurrence of œdema should be met by an increase in fat. It may be added that over 2000 German, Austrian, and Bulgarian prisoners of war occupied a compound immediately adjoining that occupied by 6000 Ottoman prisoners. Both compounds had been living under precisely the same conditions, but

<sup>1</sup> Report of a Committee of Enquiry regarding the Prevalence of Pellagra among Turkish Prisoners of War. Published at Alexandria. (Not on sale.)

not a single case developed among the Germans, Austrians, or Bulgars, whereas there were some 300 cases among the Turks in the adjoining compound. No case of pellagra occurred among the British troops. The Turkish prisoners for long periods prior to capture had been on rations considerably below the value of those they received after arrival at Kantara, and also below the standard of minimal needs, and had been subjected to great physical strain and privations.

#### GREAT MAURITIANS.

MAURITIUS, whose fate is in some places under question, although only three times the size of the Isle of Man, is—with its 370,000 inhabitants—more than twice as densely populated. With an oceanic climate and a mean temperature of 74° F., it consists of highly fruitful valleys separated by wooded spurs running up to over 2500 feet in height in several places. The island has changed hands more than once. Occupied by the Dutch in 1598, it was abandoned by them in 1710, when the French took possession, until precisely a century later it fell to the British, whose tenure was confirmed by the Treaty of Paris in 1814. French is the current language of the "Isle of France," while English is officially used in the courts of law. Dr. Joseph Rivière, of Paris, whose name heads an appeal on behalf of his fellow Mauritians to the Prime Ministers of England and France, recalls the names of a number of famous Mauritian creoles, using the term in the strict French sense. One of these, Charles Edward Brown-Séquard, son of a sea captain of Galway origin and born in Port Louis in 1817 of a Provençal mother, was an ornament alike to medicine and to his island home. His whole-hearted devotion to the cause of experimental physiology, for which he renounced a professorship in Virginia, a fashionable practice in London, and an easy competence in New York, entitles him to a place by the side of Claude Bernard, with whom he shares the honour of demonstrating the existence of a nervous mechanism presiding over the physics of the circulation. Brown-Séquard's cosmopolitan origin made it appropriate for him to preside over the Société de Biologie in Paris at the same time as he was the recipient of the Baly medal of the Royal College of Physicians of London. He died in Paris in 1894.

#### THE MORBID ANATOMY OF MALARIA.

Dr. Leonard Dudgeon and Dr. Cecil Clarke made a notable contribution to our knowledge of the pathology of malaria when, in 1917, they published in THE LANCET an account of their observations on cases of paludism in Macedonia, and more especially on the severe fatty degeneration of the cardiac muscle which they had been able to demonstrate in a certain number of cases of pernicious infection. In a second paper, which appeared in the July number of the *Quarterly Journal of Medicine*, they record the results of "An Investigation on Fatal Cases of Pernicious Malaria caused by *Plasmodium falciparum* in Macedonia." The material on which the investigation is based was collected with the definite object of correlating, as far as possible, the clinical history with the microscopical examinations, and throughout the paper this useful method of correlation has been followed. When dealing in this communication with the condition of the

cardiac muscle previously described, and which was found to be a diffuse fatty degeneration similar to what is met with in acute diphtheritic toxæmia, the authors point out that the effects of a long period of hot weather acting on men unaccustomed to such heat, and the fact that the military situation prevented the necessary degree of rest being obtained, undoubtedly played a part in the ætiology of the condition. Other matters to which special attention is directed are the hæmorrhages into the pulmonary alveoli and the pathological changes seen in the suprarenals. As regards the latter, the most constant lesion has been the reduction of the fatty lipoids of the cortical layers. In a few instances other important histological changes are noted, but the authors consider it would be incorrect to attribute the fatal result in these cases to a disturbance of the functions of the adrenals. This is important from the point of view of treatment, as experience has shown that the administration of adrenalin in such cases produces no permanent beneficial effects. This is to be expected, for the action of the drug rapidly passes off, while the gross changes in the glands are already established. There are other points of interest in this paper, which merits the close attention of all interested in the pathology of malaria. It may be mentioned that the authors found no evidence of any intracellular form of the malarial parasite. They purpose publishing further observations on the tissue changes in chronic malaria associated with grave anæmia.

#### SYPHILIS IN THE NEGRO.

In an article based on the general experience of one of the authors in dealing with syphilis in the Southern States, and upon the intensive study of 300 consecutive cases of syphilis occurring in negro soldiers, Major Loyd Thompson and Lieutenant Lyle B. Kingery<sup>1</sup> state that in the negro syphilis is contracted on an average at an earlier period of life than in the white race. Twenty per cent. of the 300 cases were patients with chancres, ranging in duration from a few days to several months. A striking characteristic was that of indolence. In the great majority of cases the chancre had been in existence for a much longer time than was usually found to be the case with similar lesions in the white race. This occurrence is attributed by the writers, who have made a careful collation of the existing scanty literature on the subject, to the fact that during the period of sexual activity the average negro has a succession of penile lesions. As regards the secondary manifestations, the writers agree with Hazen that macular and maculo-papular eruptions are not common. On the other hand, the annular lesions of early syphilis are remarkably common and may be said to be almost peculiar to the coloured race. Involvement of the mucous membrane appears to be more frequent in the negro and is often characterised by hypertrophic tendencies. The general lymphadenitis, which is confirmatory evidence of syphilis of some weight in the white, is so frequently found in the non-syphilitic negro as to be of doubtful value in diagnosis. Although there is a general consensus of opinion that the osseous system of the negro is more frequently involved than that of other races in syphilis, the writers met with only four cases in their series, but explain this discrepancy by the

<sup>1</sup> American Journal of Syphilis, 1919, iii., 384-397.

fact that their cases consisted of young individuals in whom only the secondary type of lesion, if any, would be likely to be found. The same reason accounted for the absence of any visceral involvement in their cases. As regards prognosis, the chances for recovery in the negro are not so favourable as in the white, as the large majority of the coloured race are totally indifferent to the fact that they have syphilis when no lesions are manifest, and only submit to treatment while outward evidence of the disease is present. On the other hand, the negro is less prone than the white to develop complications involving the central nervous system, especially paresis and tabes, although arteritis and aortitis are quite common and frequently fatal. The writers have been unable to confirm the statement that the negro more frequently shows a severe reaction to salvarsan than the white, as out of several hundreds of injections in the present series only two or three reactions occurred, none of which could be termed severe.

#### MEDICAL ABSTRACTS AND REVIEWS.

NEXT month appears the first number of *Medical Science: Abstracts & Reviews*, published for the Medical Research Committee by the Oxford University Press. This publication is the lineal successor of the Medical Supplement to the Daily Review of the Foreign Press, issued by the General Staff of the War Office, which made its appearance privately in January, 1918, with a view of keeping our Army Medical Staff in touch with useful enemy inventions and discoveries, soon to take on a wider character and to become a work of reference to foreign literature accessible to the medical profession as a whole. The Medical Supplement ceased with the issue of April, 1919, and the index to this truncated volume is in our hands. Serviceable as it was in the special circumstances of the time, the format was of a makeshift kind, and not a little unworthy of its contents. That is all to be made good in *Medical Science*. The first number contains 130 pages of agreeable size ( $9\frac{3}{4} \times 6$  inches), the printing easy to read, well arranged and spaced. The choice of different varieties of type for the names of authors and periodicals and for the titles of articles is judicious and might well become the standard for such things. It has, we believe, been in the minds of those who have spent much time and thought on such apparent trifles that their efforts might result in an increasing homogeneity in the publication of scientific matter. The contents consist of a series of "reviews" or critical summaries of articles on a common subject culled from various sources. Some of these, taken at random, are: spina bifida, habitual or recurrent dislocation of the shoulder, typhoid and paratyphoid diseases, dysentery, lethargic encephalitis. They occupy two-thirds of the first issue, the remainder being "abstracts," or similar critical reviews dealing with a single paper or article. In either case, the referring is done by men widely conversant with their subjects. The names on the title page of those giving editorial superintendence in the subjects named are: surgery, Mr. W. G. Spencer; medicine, Dr. J. D. Rolleston; pathology and bacteriology, Dr. W. Bulloch; neurology, Dr. F. M. R. Walshe; radiology, Dr. W. S. Lazarus-Barlow and Dr. Sydney Russ. In most cases we gather from the initials that they have actually done the work

themselves and not merely superintended the work of others. We have dealt with these external things in detail, for the publication is a novelty; how great a novelty is shown by the fact that no familiar English words occur to the mind to represent the various sections. "Review" can, of course, well be used in the sense of a Sammelreferat, but it is in common use for the critical examination of a single book. What term other than Referent suggests itself for the person who reviews and abstracts? Is there any equivalent in our tongue for Format? All this goes to show that what is being attempted by the Medical Research Committee is something which has hitherto hardly been attempted in this country in relation to medical science as a whole. There are those who contend that the Centralblatt is a growth which flourishes only in continental soil. But its foundation should be laid in industry and fair-mindedness, and these are qualities which we should like to think are indigenous. We wish every success to our contemporary.

#### THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE last meeting of the British Association for the Advancement of Science was held at Newcastle in 1916, when the proceedings were devoted entirely to the discussion of a limited number of scientific papers. In the spring of 1917, when the general outlook was black, the Council, after consultation with the local committee, decided to cancel the summer meeting which was arranged to take place at Bournemouth, this being the first time in the history of the Association that an annual meeting was not held. The annual event was resumed at Bournemouth on Tuesday last, marking the passing of the great ordeal. The President, Sir Charles A. Parsons, D.Sc., F.R.S., delivered an interesting address on the future opportunities, position, and welfare of the nation. We are gathered together, he said, at a time when, after a great upheaval, the elemental conditions of organisation of the world are still in flux, and we have to consider how to influence and mould the recrystallisation of these elements into the best forms and most economic rearrangements for the benefit of civilisation. The address presented an absorbing review of the events of the war in the light of scientific developments and applications. The subjects traversed related, naturally enough, to those great technical issues, to which Sir Charles Parsons has devoted intensive study. The position of the power resources of the nation was clearly brought forward, and the direction in which its energies should be concentrated in the future outlined in plain and convincing terms. In regard to fresh sources of power, Sir Charles Parsons revived his suggestion of tapping volcanic power by sinking a shaft to a depth of 12 miles, which would take 85 years to complete, at an estimated cost of £5,000,000. The addresses of the presidents of the various sections were delivered on Tuesday morning, and the usual reading of scientific papers followed. In these communications the speakers by common consent referred mainly to the opportunities presented to science, as accelerated in scope and processes by the war, for obtaining official recognition. The proceedings come to a close to-day (Sept. 13th).

AN INDUSTRIAL MEDICAL SERVICE.<sup>1</sup>

## III.—THE MEANS OF PROMOTING THE SERVICE.

OUR distinguished contemporary, the *Times*, has recently done good service in pointing out,<sup>2</sup> as we had already done, the development which is taking place in relation to industrial medicine. We have no doubt that employers are beginning to recognise the value of this new branch of preventive medicine; nor have we any doubt that the workers will welcome the appearance of the factory medical officer. We also entirely agree with the *Times* as to the training and knowledge required by those who undertake the work; but we feel some doubt as to the suggestions put forward that the General Medical Council should "found" a diploma in industrial medicine, and that the Royal Society of Medicine should forthwith form a section devoted to this subject. Industrial medicine must prove itself by deeds, and by showing employers of labour its economical value, and the workers its capacity for increasing efficiency and diminishing suffering. By such spade work only can foundations be laid. There is no royal road to construct a building by commencing with specious decorations.

*What Need is there for a State-recognised Diploma?*

On the side of curative medicine we do not find a diploma for the ophthalmic surgeon, another for the gynaecologist, for the rhinologist, the dermatologist, the bacteriologist, and the X-ray operator. Nor in preventive medicine is a special diploma demanded from the tuberculosis officer, the school medical officer, or the officer of the maternity and child-welfare clinic. The Diploma of Public Health as it exists to-day, though the scope of its requirements might, as Sir G. Newman has pointed out, be advantageously widened, is a sufficient portal of entry to preventive medicine. By all means let teaching authorities grant additional certificates to those who have benefited by special courses of instruction; this has long been the custom in curative medicine, and Manchester has already acted in this way in relation to industrial hygiene. Let us follow this example and avoid multiplication of portals of entry. Let us strive to obtain for industrial medicine recognition in the D.P.H. course and also in the earlier training of the medical student. The latter is a stronghold to attack, for the battlements are manned by the teaching consultants whose knowledge of general practice and of the life of the people is not conspicuous, while their acquaintance with factory life and the occupations of their hospital patients is woefully deficient. How many ophthalmic surgeons have been down a coal mine? Yet they teach on miners' nystagmus. How many dermatologists have been in an engineering factory to justify their comments on lubricant dermatitis? How many physicians have inspected the conditions under which lead-poisoning is contracted? In fine, what example do these teachers give to students in investigating at the fountain head the causation of even the obviously occupational diseases that come before them? Joseph Bells are indeed scarce.

The proceedings of sections of medical associations are liable to become far too select and specialised to recommend without urgent need the multiplication of sections; and industrial medicine to-day needs to excite interest, not to retire into seclusion. Further, anyone who has watched the proceedings of the Epidemiological and State Medicine Section of the Royal Society of Medicine must have noted that ample opportunity has been given for the discussion of industrial problems; among others, phthisis in industry; T.N.T. jaundice; industrial accidents have recently occupied the section, but the attendance at the meetings has not been such as to justify a new section.

*Bringing Conviction to the Employer.*

A more healthy line of advance is being followed in the United States, as may be seen from our report of the American Medical Association held in June last. Stress was laid on the value of medical service to industry from examples of what has already been done. "Show," said

Dr. Hastings (Toronto) "the employers of labour how the loss of 10 to 15 per cent. of efficiency in the employee could be saved, and they would be willing to put in good ventilation or any other desired improvement." Another American writer elsewhere<sup>3</sup>: "One of the greatest expenses in industry is the cost of labour turnover, and nearly 4500 new employees were examined to keep 3000 positions filled. In one department the work is of such a character that it costs \$100 to teach a new employee to become efficient." Greenwood has shown<sup>4</sup> that in this country labour turnover is much the same as in the States. We have about 8 millions employed in factories alone; let us take the annual migration of workers at rather less than the probable cent. per cent., say at 6 millions; and the cost of engagement and training at only £1 a head; we arrive at an annual charge on industry due to the present-day trial and error method of engagement of 6 million pounds. Greenwood's investigation further indicated that careful selection and supervision of workers can divide this turnover by three. Four millions so saved would far more than cover the total cost to industry of an adequate medical service; and this matter of turnover is only one of many ways in which the service would benefit industry, and through it, as no other medical service can, the health of the community.

*Avoidance of State Control.*

What is required to-day is to interest employers as the Americans are doing. A letter appearing in our correspondence columns from the director of the Industrial Welfare Society suggests that a nucleus for this interest is already existent. A further need is to avoid stereotyping functions, the result of State "recognition," at too early a stage. From this industrial medicine is suffering to-day; and one fence to be surmounted is the employer's disgust with the work of the certifying factory surgeon who is called upon by the State to undertake for 6d. work worth six times that sum, and who, therefore, does badly what he was not originally called into existence to perform. Once birth certification was established the post of certifying surgeon should have been abolished; it has only lingered on to the harm of medical progress. Let the State even at this eleventh hour abolish the post, step aside, and allow the factory medical officer to evolve naturally, his appointment being made and his services remunerated according to the laws of supply and demand.

We note with satisfaction that the new Ministry of Health shows no inclination to take a hand here. Those who direct the policy are clearly too wise and far-seeing. Knowledge must always precede progress, and industry will resent any medical service forced on it. But once employers know its value there will be no need for State action, unless it be to assist. Such assistance was recognised during the war when the salary of a factory medical officer was allowed to be charged as a working expense when calculating excess profits duty. No more was needed or is needed to-day. Industrial medicine is too vigorous a child to require the swaddling clothes of a diploma or the supporting irons of State orders to enable it to grow to a sturdy manhood.

<sup>4</sup> Final Report, Health of Munition Workers Committee.]

## PENSIONS AND ALLOWANCES FOR DISABLED MEN.

—The revised scale of disablement pensions for the higher ranks affecting soldiers and airmen comes into force as from Sept. 3rd. It provides an increase of 17 per cent. to 19 per cent., varying with the rank, on the previous rate (including bonus) for total disablement, in addition to allowances in respect of wife and children. Various alterations and adjustments have also been made for widows of men in all services. The new rates will continue for at least three years, and thereafter will be subject to readjustment according to the cost of living, but in any case they will not be lowered by more than 20 per cent., or under the previous rates (including bonus). The Ministry of Labour and the Ministry of Pensions make the following announcement:—

1. War Pensions Committees are authorised, where recommended by the medical referee, to continue to pay allowances to disabled men in training under the Ministry of Labour, over and above the training allowances which they are receiving from the Ministry of Labour for (a) "constant attendance" and (b) special diet.

2. The divisional directors of the Ministry of Labour are not responsible for the granting or payment of these allowances, which come under the heading of treatment, and any disabled men who desire their continuation or authorisation should apply to their War Pensions Committees.

<sup>1</sup> Previous articles appeared under this heading in THE LANCET of June 28th, The Need of an Industrial Medical Service, and July 5th, How to Start an Industrial Medical Service.

## THE TEACHING OF OBSTETRICS IN LONDON.

THE following is an abstract of the report made by a committee to the Council of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on the Teaching of Obstetrics and Gynaecology to Medical Students and Graduates in London.

Under their terms of reference the work of the committee fell into two parts:—(1) The present methods of teaching midwifery and gynaecology to medical students and graduates in London. (2) The changes required to make it more efficient. The committee point out the great importance of the subjects they were called upon to examine, not only to the medical profession but through it to the women of the country and to the community in general. The provision of doctors more highly trained in practical midwifery work, and the provision of adequate hospital facilities for dealing with serious complications of pregnancy, labour, and the lying-in period, are matters which are intimately related to one another, and are of equal importance to the public health. A large increase in the present hospital accommodation for midwifery cases in London is as urgently needed as an improvement in the training of medical students. And, further, if by suitable arrangements better training in the management of infants could be associated with midwifery training, a great advance would be made in dealing with the difficult problem presented by the high rate of infant mortality.

### A.—The Present System: Midwifery.

*Systematic teaching.*—Systematic lectures are given in all the hospitals by the obstetric physicians, usually in the summer term—i.e., once a year only: the number of lectures varies from 20 to 40. A "practical midwifery" course, which includes operative demonstrations on the dummy, is also given either by the obstetric physician or by the tutor. In the latter case it is combined with the tutorial class. In most hospitals the regulations provide that students attend the systematic lectures and the practical midwifery course before being allowed to attend cases of labour. The Dean of the school may, and sometimes does, suspend this rule.

The tutorial or revision classes are held each term by the tutor, and are attended mainly by the students then preparing for the examination in midwifery and gynaecology. Attendance at the systematic and practical midwifery courses is compulsory under the regulations of the examining bodies. Attendance at the tutorial classes is optional, but in practice all students do attend.

*Clinical instruction in normal and abnormal pregnancy.*—Systematic instruction is given in the gynaecological wards and out-patients' departments of all hospitals on the diagnosis and management of pregnancy, the clinical material consisting of such women as present themselves for one reason or another during pregnancy. Pregnant women who desire to be attended at their own homes are usually required to present themselves at the hospital for examination beforehand. They are seen, usually, by an obstetric physician or by the tutor, and any students who care to attend are present and are allowed to examine the patients; the attendance of students is, however, not as a rule compulsory, and in practice sufficient use is not made of this department for purposes of teaching. Except in the case of hospitals with a midwifery ward, this is all the provision which is made for instruction in normal and abnormal pregnancy.

*Clinical instruction in the conduct of labour.*—In four hospitals midwifery wards are established for the instruction of medical students; others have a midwifery ward which is used chiefly for training midwives; for the purposes of this report these are of no value. The remaining hospitals have no midwifery wards at all at the present time. In every hospital serious complications of labour can be admitted to the gynaecological beds, where they come under the charge of the obstetric physicians; in many cases, however, the registrar actually deals with them.

In the case of hospitals with no midwifery ward the training of students in the actual conduct of labour, normal and abnormal, is practically non-existent. In order to attend the 20 cases required by the regulations of the examining bodies the student is attached to the maternity district of his hospital; previous to this he has attended the lectures mentioned above, and, in addition, in some hospitals special demonstrations are given by the tutor or the resident obstetric officer to each batch of students before going on the district. As a rule, however, the students of hospitals with no midwifery ward have never seen women in labour before going on the district to attend them.

Every hospital has a regulation that the student is to be accompanied to the first case or the first two cases by the R.O.O., but this regulation cannot in all instances be carried out, and the student not infrequently goes to his first case alone. It is assumed that he needs no assistance after the first two cases in conducting a normal labour, but he is under instructions to report at once to the R.O.O. any abnormal conditions which he may discover. His ability to detect abnormal conditions is, however, very small from lack of training. At one hospital a trained midwife in the service of the hospital is also present at every labour, and gives the student assistance; as a rule the student conducts normal cases without any assistance, even in respect of the toilet of the infant. Abnormal conditions are frequently dealt with by the R.O.O. in the patient's home; practically all hospitals have a rule that serious complications, such as ante-partum hemorrhage or eclampsia, should be at once transferred to the hospital, where they are admitted under the

supervision, usually indirect, however, of the obstetric physicians. There the student is able to take part in their management, and to see any obstetric operations which are required.

The student continues to attend his district cases during the first seven to ten days after the puerperium, under the same instructions to report any abnormal conditions which may arise regarding either the mother or the child. It must be recollected that unless he has previously attended the midwifery ward the student has received no practical instruction whatever in the management of infants; as a rule his work is done without any systematic supervision during the puerperium.

In some hospitals the number of cases available in the district is insufficient to allow 20 for each student; a certain number of students from these hospitals are sent to the lying-in hospitals, where they can be "signed up" for 20 cases in 14 days (Queen Charlotte's), 21 days (York-road), or 14 days (City of London). In some instances the student goes for a fortnight to the Lying-in Hospital, and then serves for a fortnight on the district of his own hospital.

In the case of the hospitals having a midwifery ward for students, the conditions require separate notice. The number of beds in these midwifery wards varies from 8 to 24; the number of cases admitted per annum varies from 180 to 550 to 600; the number of cases admitted per student trained varies from 3 to 11 or 12. The number of cases actually delivered by medical students in the ward is limited, in all but one hospital, by the fact that, not being in residence in or near the hospital, they only attend the deliveries which occur in the daytime. The instruction is given in part by the visiting physicians, but mainly by the registrar or the resident officers. The period of attendance in the midwifery ward is four weeks, and the student is not permitted to begin attending cases in the district until he has conducted a certain number of deliveries in the ward and received a certain amount of practical instruction. After this he attends his district cases alone, as do the students of the other hospitals.

*Maternity and infant-welfare centres.*—These centres, where they exist, provide opportunities for instruction in the care of the nursing mother, in infant feeding, and in the general management of the infant during the first year of life. The midwifery department of a hospital ceases to be concerned with the average normal case in 10 to 14 days after delivery; the work of these centres is a continuation of the work of the obstetrician, and its utility from the point of view of preventive medicine is generally recognised as being very great. It is of the first importance that these centres should be made use of in training students in continuation of their midwifery work, yet only five hospitals have a maternity and infant-welfare centre in connexion with them. Others are soon to be started.

### B.—The Defects of the Present Methods of Teaching Midwifery.

The systematic instruction given is, generally speaking, satisfactory, and is in the hands of the obstetric physicians. The practical instruction leaves very much to be desired, and in some respects merits emphatic condemnation. We desire, however, to acknowledge the great improvement which has followed the establishment of midwifery wards for the instruction of medical students. The change is of recent date and is at present operating in only four hospitals; but its great usefulness is apparent and will receive general acknowledgment. The case of the hospital having no midwifery ward for students is the least satisfactory; the additional experience which may be obtained when the student also goes to a lying-in hospital for a short time is most unsatisfactory. The following considerations must be borne in mind:—

(1) *The hospital without a students' midwifery ward.*—The grave defects of this system may be set out as follows:

(a) Students learn to deliver women only under conditions in which surgical cleanliness is extremely difficult to secure. Under a satisfactory system the same principle should be followed as obtains in general surgery—viz., they should be taught upon the highest plane of efficiency which it is possible to attain, not upon the lowest, which can be reached without unjustifiable risk to life. A not unfair analogy would be for surgeons to teach students the technique of abdominal operations under conditions where they would be deprived of adequate light, ventilation, and the means of cleanliness.

(b) Students who are taught thus, under makeshift conditions, will absorb the impression that careful and exact precautionary measures are unnecessary. The effect of such an impression upon their future work in private practice can only be disastrous, and may be related directly to the incidence of puerperal fever in the country as a whole.

(c) Unless complications occur in his district cases, he will never see the obstetric physicians dealing with labour at all; and even when patients are transferred to the hospital the control of the obstetric physician is often indirect, and is exerted through the registrar or R.O.O. who actually deal with the cases themselves after asking his advice. The student, therefore, learns extremely little of abnormal labour; he may not see a forceps delivery during his month, and in occasional instances may go up for his final examination without having seen this procedure except upon the dummy.

(d) It follows from (c) that the student learning clinical midwifery is completely out of touch with his senior teachers; he does not see them actually engaged in the work he is trying to learn, and never has the advantage of their supervision and guidance.

(e) That a student should conduct deliveries in the district is undoubtedly useful, for the single-handed conduct of cases of labour may be assumed to develop his sense of responsibility, a valuable aspect of his training as a doctor. But this should come after and not before he has been made acquainted with the nature of his task. In the case of the student of average ability, to thrust responsibility upon him before he has been taught his work, will be more likely to hinder than to help him in learning.

(f) Attendance upon 20 to 30 cases of midwifery ought to afford invaluable opportunities of instruction and experience in the management of the normal puerperium, of minor disorders of the puerperium, and of infant feeding. Under the district system these opportunities are completely wasted, owing to the total lack of systematic supervision of the students when at work.

(2) *The lying-in hospital.*—The great defect here is that no direct provision is made for the instruction of medical students at these hospitals.

They attend the practice of the hospital in order to be "signed up," but no one is responsible for teaching them. The visiting physicians pay regular visits to the lying-in wards, where they are followed by a mixed class of graduates, students, and pupil-midwives, to whom they give what instruction is possible in the circumstances upon the puerperium and the management of infants. They rarely, if ever, conduct a case of normal labour, and are seldom in the labour wards except for difficult cases which require their presence. "Waiting cases" which present abnormal conditions are usually seen by the visiting physicians, who may demonstrate them to the students; but under the rules of the hospital the visiting physicians do not undertake any responsibility for the instruction of medical students. It has been already stated that the student does not actually deliver all the patients he is certified to have "attended"; it suffices if he is present at the delivery as a spectator. The number he actually delivers is variable and depends upon the goodwill of the R.O.O. and the resident midwives, either of whom may supervise his work. Instruction of students is, however, no part of their duty to the hospital and they are under no obligation to take pains in giving it. Some students may be allowed by the R.O.O. to conduct a forceps delivery under supervision, but this depends entirely upon the goodwill of the R.O.O. himself.

(3) *The hospital with a student's midwifery ward.*—This system undoubtedly marks a great advance in the training of students, but certain defects are inherent in it. Only four hospitals have such a ward in actual working; its size varies from 8 to 24 beds. The greater number of cases admitted are normal cases. Students are attached to the ward, in all cases exclusively, for a period of four weeks. They come into close touch with the obstetric physicians, who demonstrate cases to them and give general clinical instruction on their regular visiting days. The women are delivered by the R.O.O. or the resident sister midwife, under both of whom the students work, and by whom they are personally instructed in the conduct of normal labour. The students are not in residence except in the case of one hospital, and, as a rule, only the daytime labours are seen by them. It must be pointed out, however, that the visiting physicians take little or no part in teaching the conduct of normal labour, that the more serious cases of abnormal labour are not all seen by them, and even when conducted under their supervision, they are not necessarily delivered by them.

The small size of the midwifery ward is one of its chief defects. It suffices to allow each student to conduct a small number of normal deliveries before commencing his work on the district; this number could with advantage be much increased. The more serious abnormal cases from the hospital district are sent in to the midwifery ward, but it is impossible for these wards to deal with large numbers of abnormal cases, and there is no doubt that the students' opportunities of seeing difficult labour dealt with are inadequate.

The non-continuous character of the student's attendance, in all but one hospital, is a grave disadvantage. A large proportion of all deliveries occur at night, when the student is not there to see them. Complicated cases may occur at any time, and from their nature the great majority must be dealt with promptly. As a rule, they cannot be left over until the hours of the student's attendance come round, and thus invaluable opportunities of instruction are lost. To tell the student all about a difficult case the day after it has been dealt with is not a satisfactory method of clinical instruction. The time the student devotes to the midwifery ward (four weeks) is quite inadequate, if his attendance is only in the day time, and even that may be broken up by other duties.

The bulk of the practical teaching in the midwifery wards is given by the registrar and the R.O.O., particularly in regard to the conduct of normal labour; whereas the student ought to be taught both normal and abnormal conditions by senior obstetric officers of greater experience and higher standing than the average registrar. The major part of the student's clinical teaching in surgery is given him by surgeons and assistant surgeons, and this is universally regarded as being necessary. It is equally necessary that he should be taught his clinical midwifery by men of similar standing. In the nature of midwifery work this would involve the presence in resident control of the midwifery ward of senior officers, who would be always available, would personally supervise the work of the labour wards, and would themselves deal with abnormal cases at whatever hour they might arise.

### C.—The Present System: Gynecology.

A certain small number of systematic lectures in gynecology are given by the obstetric physicians either as a part of the course of midwifery or separately. As a rule the student clerks for one to two months in the gynecological department; although the regulations of the majority of the examining bodies require him to spend three months at clinical gynecology, the hospitals do not all enforce it. In some instances his gynecological clerkship is done in the same month as he attends his midwifery cases on the district. The number of gynecological beds in the various hospitals varies from 11 to 34, the average being about 20. In the wards the clerk is taught by the registrar or the R.O.O. to take the history of a gynecological case, and is usually taken over the physical examination by the same officer. He follows the obstetric physician in his rounds, and is present at the operations which take place during his clerkship. His attendance in the wards may be much restricted if he is at the same time doing his midwifery cases on the district. In the wards he gets certain opportunities of making pelvic examinations under anaesthesia, and of personally assisting at operations. The operations and the operation specimens are demonstrated more or less fully, according to the custom of each operator and the amount of work he may have to get through. In the case of hospitals with only 10 to 20 gynecological beds the number and variety of cases seen in a month is necessarily very limited, and is, in fact, quite inadequate as a course of clinical training.

Among gynecological out-patients, the student usually sees a large number of minor cases, and is allowed to examine a fair proportion of them. He needs close supervision and a good deal of assistance in learning to make the bi-manual examination, and in the case of a large out-patient clinic the number of cases which have to be seen precludes the out-patient physician from devoting close attention to the student. In a small clinic the number and variety of the cases seen by the student in one month is quite inadequate. As a rule, the out-patient physician is assisted by the R.O.O., but it is rare to find any system operating for the sifting of cases, so that those most suitable for teaching may be

passed at once to the out-patient physician. Usually the R.O.O. sees all the old cases and the out-patient physician all the new ones irrespective of their clinical importance.

*Deficiencies in gynecological training.*—It is in the clinical training of the students that defects are most apparent. These deficiencies can be traced mainly to two causes: (1) The very inadequate number of gynecological beds in all the hospitals; (2) the very inadequate amount of time which the student devotes to the subject. With regard to the number of beds it must be recollected that midwifery and gynecology together form one-third part of the final examination, and are associated on equal terms with medicine and with surgery. The combined number of gynecological and midwifery beds available for teaching is less than one-third of the number allotted either to medicine or to surgery. This policy of cramming the work of the obstetric physician is due partly to the failure of colleagues to realise the importance of these subjects to the medical practitioner and to the community and partly to the relatively low level of the requirements of most of the examining bodies. In both medicine and surgery the student is obliged to clerk for six months, while to clinical midwifery and gynecology combined he does not devote more than three months at most hospitals.

### D.—The Consequences of Defective Training in Midwifery and Gynecology.

(a) The training of medical students is a matter of the first importance to the State, for efficient doctors are necessary to the maintenance of the public health. In the early years of his private practice midwifery and the minor ailments of women and infants form a large proportion of the young doctor's work, and yet these are probably the subjects in which his practical training has been most deficient.

(b) Since the great majority of students learn to conduct labour only under conditions in which surgical cleanliness cannot be enforced, they carry with them into practice the impression (perhaps subconsciously) that surgical cleanliness is not of the same importance in midwifery as in surgery. The makeshift methods with which they begin their experience tend to become stereotyped in their minds, and the effect of this upon their work in private practice must be very bad.

(c) The bearing of this point upon the incidence of death from child-bearing in the country cannot be overlooked. During the period 1891 to 1914 this death-rate of childbirth for Great Britain and Ireland was almost stationary, the fall being only from 5.8 to 5.08 per 1000 births. This can only be regarded as extremely unsatisfactory, for it shows that during a period in which surgical training made such rapid advances midwifery training made none. Indeed, in all divisions of the country except Ireland the death-rate actually rose in the quadrennium 1911-1914. The conclusion cannot be avoided that both medical students and midwives are being imperfectly trained.

(d) The student has been accustomed to pay only perfunctory attention to the puerperium, for he has been left largely to himself at this period while attending his cases on the district; he therefore cannot be expected to realise its importance from the point of view of the health and working efficiency of the mother.

(e) The average newly qualified doctor has had little or no clinical training in the management of the infant and usually leaves it entirely to the nurse. Even in the case of the well-to-do the nurse often regards the infant as her patient, and feeds it or dresses it without reference to the medical attendant. Mothers also come to think that this is the proper arrangement and to prefer the advice of the nurse. There is no doubt that many infant lives are lost owing to the fact that medical students receive insufficient clinical training in this subject.

(f) It is the personal experience of all the members of your committee that medical practitioners do not consider it necessary to obtain the services of a specialist or of a hospital in the emergencies of midwifery to the same extent as they undoubtedly do in the case of general surgery. This is largely due to the fact that they have not, during their training, seen such cases dealt with by the senior obstetric officers in the way that they have seen serious surgical cases dealt with by surgeons. Their custom is to call in a neighbouring practitioner and to do the best they can.

(g) The lack of hospital accommodation for women in labour and the lack of public means of transporting patients to hospital tend to confirm the practitioner in this attitude.

(h) The close relation which subsists between bad midwifery and pelvic disease in women is well recognised. A sound practical training in the recognition and treatment of pelvic disease is as important as the midwifery training itself. Young medical practitioners are probably less able to recognise common forms of gynecological disease than they are common forms of medical or surgical disease. The results are very serious in regard not only to the life, but also to the health, working efficiency, and subsequent capacity for child-bearing of the women of the country.

### E.—The Bases of an Efficient Training in Midwifery and Gynecology.

(1) Owing to their intimate relationships these subjects should be taught, as is the British practice, by the same teachers, and the training of students in them should run concurrently.

(2) Midwifery training should be extended in one direction (antenatally) so as to comprise a fuller study of the whole course and management of pregnancy, and in the other (post-natally) so as to comprise the management of the whole nursing period and the management of the infant.

(3) The management of labour should be taught as a surgical procedure; this can only be done in hospital, under surgical conditions, with adequate equipment, and a highly trained staff of teachers. Owing to the peculiar nature of the work the senior officers upon whom the ultimate responsibility rests should be resident in the hospital, or should be available at any time their presence may be required.

(4) There should be adequate hospital accommodation in all large centres of population to allow of all serious obstetric emergencies being immediately admitted for treatment; this is recognised as being necessary in respect of surgical conditions, and it is equally necessary in respect of midwifery.

(5) From (4) it follows that the number of beds available for cases of midwifery must be very largely increased, allowing due provision to be made for the emergencies which so frequently arise.

(6) Medical students and midwives cannot be suitably trained in the same institution unless in separate classes.

(7) The proportion of beds allotted to midwifery and gynaecology is quite inadequate to the importance of the subject from the point of view of the public health; the number should bear a definite proportion to the total number of beds in the hospital; at the present time the average proportion is less than one-twentieth of the total in the 12 teaching hospitals; this proportion should be increased to at least one-tenth. A considerable number of gynaecological cases are dealt with by the surgeons in the surgical wards, which are largely lost for teaching purposes.

(8) The requirements of the examining bodies in both subjects should be strengthened so as to enforce (a) an adequate period of clinical training during which the student should be allowed to undertake no other work; (b) the provision of suitably arranged and sufficiently large facilities for clinical work.

(9) The extent to which the student's training is influenced by the nature of the qualifying examination must not be overlooked, and the present system of examination in midwifery and gynaecology urgently needs amendment. The examination of the Conjoint Board, for example, is very unequal owing to the large number of examiners from different teaching hospitals in London and from provincial universities, who often set widely different standards. And the absence of a clinical examination in both subjects leads the student to neglect his clinical work and to underrate its importance.

The examining authorities should be urged, whenever it is possible, to recognise the principle that the student should be examined by his own teacher with a second examiner as assessor, and that clinical examinations should be accorded the same importance as in the case of medicine and surgery.

#### F.—Sketch of a Satisfactory Scheme.

(I.) There are two different lines upon which fully equipped departments, of adequate size, for the teaching of midwifery and gynaecology could be organised:—

(a) Certain of the larger teaching hospitals might provide for a great expansion of their existing midwifery wards, from which, with their associated gynaecological, pathological, and other services, a midwifery department could be formed capable of providing for the training, not only of their own students, but also, if necessary, of students from other hospitals where there is no midwifery ward in existence.

(b) New centres might be found in outlying districts where there is at present no adequate maternity service. These new centres, though not in proximity to existing teaching hospitals, might be affiliated to certain of them which were unable to develop fully equipped maternity departments of their own, and which might send their students to the new centre for training. These new centres could be made use of for training not only students but also post-graduates, and in addition they would afford much-needed facilities for research.

(II.) Departments developed out of existing maternity wards at a teaching hospital (Subsection I.a) ought to provide a minimum of 75 beds, of which 50 would be for midwifery and 25 for gynaecology. Of the midwifery beds a certain number would be allocated to ante-natal conditions and puerperal complications. "Departments" developed in connexion with the larger teaching hospitals, which have greater facilities for expansion, might exceed these figures if students from other hospitals were received in addition to their own.

In the opinion of the committee a midwifery department containing less than 50 beds cannot be satisfactory for the teaching of students, as it will not afford them an opportunity of seeing all the ordinary difficulties and complications of pregnancy and labour during the limited period of time in which they are attending the department. It would be impossible for every one of the existing teaching hospitals to supply such a large number of beds for midwifery. So it is obvious that under this scheme some form of concentration would be necessary—that is, that some of the hospitals should provide midwifery departments which would be attended by their own students and, in addition, by students from the hospitals which were unable to provide such departments.

(III.) Newly founded centres (Subsection I.b) would probably be much larger than the "departments" on account of the urgent public need which exists for increased hospital accommodation for midwifery cases. They could provide about 200 beds each, of which, roughly, 20 would be for ante-natal conditions, 100 for labour, 20 for infective cases (isolation), and 60 for gynaecological cases. The provision of a certain number of such centres as these in selected outlying districts would form a most valuable contribution to the provision of an efficient maternity service for London. It is obviously of great importance that full use for teaching purposes should be made of such new centres when they come into existence.

The provision of a proportion of gynaecological beds in the centre is an essential feature of the scheme. It would be needed to meet the medical requirements of the district, and, further, it would allow the student to do his practical work in the two subjects together and under the same teachers; knowledge of either subject is incomplete without the other, and the student learns them together much more readily than separately.

(IV.) The medical staff required to work the "centre" also involves a new departure. Reasons have been advanced for the view that a much larger proportion of the teaching in the conduct of normal and abnormal labour should be given by senior obstetric officers, than is the case at present. This involves senior officers being either in residence at the centre or on duty during certain definite hours of the day and night. Such services could not be required of them without payment upon an adequate scale. Next to them would be required assistants in residence, of the status of the present registrar or tutor, whose whole time would be required, and who also must be adequately paid.

(V.) "Departments" developing out of existing midwifery wards at teaching hospitals (Subsection II.a) would probably be best staffed as follows:—

(1) A staff of two or more visiting obstetric physicians (or surgeons) who would, in rotation, undertake the duties appertaining to the director or chief of the department, for definite periods as might be most suitable.

(2) A resident "*chef de clinique*," appointed for a term of years, who must be a whole-time officer, and who would have charge of the department under the visiting staff. His professional status should be above that of an obstetric registrar—i.e., comparable with that of a resident assistant surgeon or a resident assistant physician.

(3) One or two resident senior assistants of the status of the registrar, who would direct the students personally in their work in the labour wards, the lying-in wards, and on the district, and a number of resident assistants (house surgeons). These would also be whole-time officers.

Departments such as these would probably eventually develop into "units" with professors of midwifery and gynaecology, on the lines of the units of medicine and surgery which are about to be founded. Such professors of midwifery and gynaecology should not be "whole-time" professors, but should remain in touch with consulting practice.

(VI.) New centres formed in outlying districts (Subsection II.b) would probably be best worked by:—

(1) A resident director or superintendent, who might be appointed for a term of, say, five to seven years. He would be of the status of an obstetric physician at the teaching hospital. He would be responsible for the control of the work of the institution generally, and would take a large share in operative work, in teaching, and in research. The director should not be a "whole-time" officer, but should remain in touch with consulting practice.

(2) One or more resident assistant directors.

(3) Working under (1) and (2) a sufficient number of resident assistants to direct the students personally in their work in the labour wards, the lying-in wards, the gynaecological wards, and in the district. They would also be responsible for the clinical pathology of the centre, and would carry out research under the supervision of the director and the assistant director.

These appointments when first instituted would afford an opportunity for the teaching hospitals affiliated to the centre to be represented upon its teaching staff, and thus keep the students in touch with their own hospital staff.

It must be borne in mind that outlying districts which are in need of a midwifery hospital service require general hospitals as well; these would, no doubt, eventually be established, and thus provide for the association of pathological and other services with the new centres.

(VII.) In the opinion of the committee the requirements of the students' training can only be completely met under the scheme of new "centres," on account of the necessity which has been already emphasised of the senior teachers taking a considerably larger part than at present in the work of clinical instruction. Under the alternative scheme of "departments" at existing teaching hospitals the senior teachers would, in effect, not take any larger part in teaching than they do now.

(VIII.) Students belonging to hospitals with a fully equipped midwifery department (Subsection I.a) should be attached to the department for a period of four months, during which their whole time would be devoted to midwifery and gynaecology, and they would be in residence for, at any rate, a part of the time. Students from other hospitals would probably come to the department for practical midwifery only; they would be in residence for at least one month. In the second month they would attend their cases on the district of their own hospital under the supervision of their own medical staff, and would, in addition, continue to attend the department for clinical teaching, operations, &c. These students would receive their gynaecological training at their own hospitals, as at present.

(IX.) The midwifery districts of the teaching hospitals would, therefore, be continued, for it is of great importance that the student should have experience of district work during the latter part of his training, as long as it is under proper supervision. In the case of certain hospitals the district could not provide sufficient cases to enable each student to attend the required number. Arrangements could, perhaps, be made for a proportion of the students from these hospitals to do their district work elsewhere—i.e., in the district of another hospital.

(X.) Each teaching hospital should provide means of properly supervising its students in their work on the district. Under the present system the assistant obstetric physician is in nominal charge of this work, with the assistance of the registrar and the R.O.O. The control of the assistant obstetric physician should be made effective under the rules of each hospital, and the duties of the registrar should include the instruction of each student in the management of his district cases during the puerperium.

(XI.) Students attending a new centre (Subsection I.b) would be attached to it for a period of four months, during which their whole time would be devoted to midwifery and gynaecology, and they would be in residence for, at any rate, a part of that time.

#### G.—First Steps to be Taken.

(I.) While the committee are of opinion that eventually the foundation of new "centres" will be necessary for the proper training of students in midwifery and gynaecology, it is recognised that it will probably be some time before such a scheme could be put into operation. The necessity of taking steps promptly to effect the most urgently needed improvements is, however, obvious, and the formation of "departments" at existing teaching hospitals (F, Subsection II.a) could be put into operation without prejudice to the later formation of new "centres." In this way the two schemes could be developed side by side, and there is no doubt that the one found by experience to be best suited to the special requirements of London would eventually prevail.

(II.) It is of great importance that a "department" of the size indicated, formed at a teaching hospital, should in addition to their own students receive a certain number of students from one or more hospitals which have no midwifery ward. If this plan were carried out the existing inequality of the training in practical midwifery in London which results from the absence of a midwifery ward in many teaching hospitals would be to a great extent obliterated, and the general level of midwifery training would be at once appreciably raised.

(III.) As hospitals without a fully equipped midwifery department would continue to train their own students in gynaecology as at present, an immediate increase in the number of gynaecological beds at these hospitals is urgently required for the reasons which have been already stated.

(IV.) The first steps to be taken would probably be to inquire into the following points:—

1. (a) The possibility of the hospital designated being able to allot the required number of beds to midwifery.

2. (b) The willingness of other hospitals to make use of the "department" for training their students.

3. (c) Suitable financial arrangements being made between the affiliated hospitals, assisted by a Government grant.

(V.) Another development which might be put into immediate operation is the much greater utilisation of ante-natal and infant-welfare clinics for the instruction of students.

(VI.) It is also very desirable that all teaching hospitals should, as far as possible, compel their students to give up a minimum of four months solely to midwifery and gynaecology, and the examining bodies should be moved to alter their requirements in this sense.

#### H.—The Teaching of Graduates.

##### Midwifery.

(1) There is no doubt that it is very desirable that provision should be made for the clinical instruction of graduates in midwifery; there is a considerable demand for it now, and this demand is likely to be greater in the future.

(2) The essential conditions for the practical instruction of graduates in midwifery are: (a) an institution able to receive large numbers of cases, and making special provision for difficult and operative labours; (b) resident teachers of status and experience.

(3) The case of the medical student is in our opinion more urgent than that of the graduate and should be dealt with first. When large central institutions on the lines indicated above have been set up there will be no difficulty, in addition to meeting the needs of the students, to provide the clinical material, the teachers, and the laboratory facilities which are requisite for the instruction of graduates.

(4) Under the conditions which exist at present it is practically impossible to organise post-graduate instruction upon satisfactory lines. Certain suggestions for improving the existing facilities at lying-in hospitals will be found in Appendix D.

##### Gynaecology.

(1) The abundant clinical material of the special hospitals for women is largely lost for teaching purposes under the present conditions. A certain number of clinical assistants (qualified) are usually attached to them who attend out-patients and operations, but there are no systematic arrangements for clinical teaching upon a considerable scale.

(2) Those hospitals would be of invaluable service in providing clinical teaching for graduates, and this appears to be their proper educational sphere.

(3) The three principal hospitals (Chelsea Hospital for Women, Samaritan Free Hospital, Soho Hospital) should be affiliated, so that graduates taking a course would be entitled to follow the practice of all of them. In this way graduates taking a course of clinical gynaecology could be continuously employed in out-patient departments, wards, operating theatres, and laboratories.

(4) Courses of instruction lasting for six to eight weeks should be provided—viz., (a) clinical gynaecology; (b) operative gynaecology;

(c) gynaecological pathology.

*Clinical gynaecology.*—Demonstrations on selected cases should be given in the in-patient and out-patient departments, and the senior and junior members of the staff should take part in the teaching in both departments. Facilities should be afforded to each graduate to acquire a knowledge of the bimanual methods of examination by repeated practice while the patient is anaesthetised; to acquire a knowledge of the instruments, appliances, &c., used in the practice of gynaecology. Case-taking cards should be provided in both in- and out-patient departments.

*Gynaecological pathology.*—Instructions should be given in (a) recent specimens, (b) microscopic preparation, (c) bacteriology, (d) specimens in the Museum of the Royal College of Surgeons.

(5) Advanced courses might be arranged for those who desire to specialise in gynaecology, and opportunities afforded them both in the wards and in the laboratory for research.

(6) Clinical assistantships might still be available for those who, having taken a post-graduate course, desire to continue their work at the hospital.

The report is signed by Dr. T. W. Eden (chairman of the committee), Dr. H. R. Andrews, Dr. G. F. Blacker, Dr. J. S. Fairbairn, Dr. F. J. McCann, and Mr. Gordon Ley (secretary).

1 Bottles overflowed.

2 The water was dark violet in colour.

Tr. = trace.

"Tar" includes all matter insoluble in water but soluble in CS<sub>2</sub>. "Carbonaceous" includes all combustible matter insoluble in water and in CS<sub>2</sub>. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 9 lb. per acre; (b) 2.56 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

## THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund was held on Thursday, July 31st, at the offices of THE LANCET, when the following final balance-sheet was presented by Dr. Des Vœux, the honorary treasurer:—

### BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

*Treasurer's Cash Statement from Commencement to Close of Fund, July 24th, 1919.*

	£	s.	d.		£	s.	d.
Donations and sub-				Relief ... ..	25,766	4	11
scriptions ... ..	25,790	11	6	Loans not repaid ...	97	8	0
Interest received ...	1,143	12	7	Drugs ... ..	250	16	8
				Clothes ... ..	344	17	0
				Auditors' fees ... ..	16	16	0
				Printing and stationery	199	14	3
				Postages and sundry			
				expenses... ..	46	19	2
				Balance for final dis-			
				tribution... ..	211	8	1
	26,934	4	1		26,934	4	1

We have examined the above account with the books and vouchers of the Fund and certify it to be correct according to the books. In our opinion the receipts and payments have been fully recorded, and we have compared the receipts with the published acknowledgments and have had certificates of the balance produced to us from time to time. The above account incorporates the periodical accounts which we have previously certified.

CREWSDON, YOUNG, AND HOWARD, Chartered Accountants.

70A, Basinghall-street, London, E.C. 2, 24th July, 1919.

It will be seen that the Committee, by judicious investment and husbanding of their resources, were enabled to maintain the Fund in its charitable capacity while actually disbursing £800 more than was received from subscribers.

The Committee decided to pass no resolution at the time with regard to the disposal of the small balance remaining in the treasurer's hands, as certain expenses of printing and publication might yet have to be incurred.

Dr. Squire Sprigge, the honorary secretary, offered to keep the papers and books having reference to the Fund at the offices of THE LANCET for the present.

## THE POSITION AND PAYMENT OF THE PENSIONS BOARDS;

### DEPUTATION TO THE MINISTRY OF PENSIONS.

As will have been made clear by communications to our correspondence columns for some time past, medical men serving on Pensions Boards are not altogether satisfied with the conditions of service and with the remuneration offered. On Sept. 4th a deputation from the British Medical Association waited on the Minister of Pensions at Westminster House to bring these matters before his notice. The deputation included the responsible officers of the Association, and was received by Sir L. Worthington Evans, with whom were Lieut.-Colonel A. L. Webb, Dr. R. Cunyngnam Brown, and Mr. J. F. Christie.

Dr. T. W. H. GARSTANG, as spokesman of the deputation, said that there were six main points which it had been decided to bring to the notice of the Minister. These were:—

1. That the fees for doctors attending boards under the Ministry of Pensions should be raised from the present standard of 1 guinea to 2 guineas.
2. That the specialists' fee be advanced pro rata.
3. That the number of cases to be seen in an individual session should not exceed eight.
4. That the length of the session should not exceed 2½ hours.
5. That payment to doctors attending on these boards be made more promptly than at present.
6. What was the policy of the Ministry as regards throwing open the posts of medical referees to men who had returned from the Services, and when was this policy likely to be carried out?

Dr. Garstang and several other members of the deputation explained the general feeling of the medical profession that the 1 guinea fee was inadequate, and that it had only been accepted as a temporary measure, owing to the anxiety of the profession to help the country during the war. Now that the war was over the Ministry could not expect to have this work done at an admittedly inadequate rate and still retain a choice of the best men. Chapter and verse were given for the other grievances alleged.

Sir L. WORTHINGTON EVANS, while assuring the deputation of the careful consideration of all their points, indicated that the suggested increase in the sessional fee to 2 guineas would probably cost the country over £1,000,000 a year—an increase in expenditure not to be lightly undertaken. As regards the number of cases examined in a session, it was found that the average had for some time been 7·2 cases, and latterly even less, and he thought that if that was so it should be considered as having met the point submitted. He was entirely in agreement as to the length of the session being 2½ hours, though he pointed out that there would every now and then be occasions on which, for the sake of dealing with a case which might have come some distance, the members of the board should be willing to extend the time of the session a little. He considered that there must be some give and take in the matter. He offered to look into the question of prompt payment, as, in his opinion, there should be no arrears such as had been mentioned. As regards the posts of medical referees, the District Commissioners had been instructed some time back that, as soon as they knew that practically all the doctors had returned who were likely to apply, the posts should be thrown open, preference being given in the following order:—

- (a) Service overseas.
- (b) Service in this country.
- (c) Men who had already held the posts.

Action, he added, had been somewhat delayed owing to the rearrangement of the administrative areas of the Ministry, but in Scotland this was now complete, and the procedure mentioned would be put into operation almost at once; Wales would shortly follow suit. Similar action would be taken in other districts as soon as the District Commissioners reported that the bulk of the men had returned.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *A Monument to Medical Men Killed during the War.*

A PROPOSAL has just been made to commemorate by a monument those medical men who have been killed by enemy action. M. Landouzy, the dean of the Paris Faculty of Medicine, has had their names engraved on a tablet on the walls of the great hall of the faculty since 1915. A form of monument had actually been proposed, consisting of names engraved on a wall, framed by plaques of mosaic, and surrounding a statue representing military courage. Since then, however, the number of victims has increased considerably. The French Medical Corps consider that the monument should be proportionate to the magnitude of the sacrifice and the number of the heroes. The idea is to honour the dead not only of Paris but of the whole of France, and new projects are on foot. One suggestion was the erection of a monument on the Boulevard St. Germain, in front of the entrance to the Faculty of Medicine, but this was thought to be lacking in originality and possibly in discretion. Up to the present nothing has been decided except the main principle of opening a subscription list among medical men in France, and including also old students of French universities now living abroad. The scheme most likely to be adopted is that supported by the present dean of the faculty, Professor Roger, which comprises the rebuilding of the old eighteenth-century amphitheatre of the School of Surgery on a more suitable site near the faculty. This old building is doomed to destruction, and the beauty of its architecture would justify its reconstruction in the form of a small temple, with marble slabs on which could be engraved the names of medical men who had fallen in the service of their country.

### *Influence of Orientation on the Physiology of Man and Animals.*

A curious communication by M. Jules Regnault to the French Society of Comparative Pathology again brings up the question of the effect of the earth's magnetism on the physiology of living animals. Some such influence has been suspected from the earliest times. In 1845 Reichenbach observed that certain people experience real discomfort when facing east, even when unaware of their position. During the last two years M. Regnault, following up

the experiments of Abrams, has convinced himself that if, after having percussed out liver and heart with the subject facing west, the observer repeats the percussion with the subject facing north, east, or south, the area of dullness is found to be perceptibly smaller. Other experiments show that visceral reflexes react most strongly to electro-magnetic or electric stimuli when the subject faces west. These facts correspond, moreover, with those recorded by M. Raphael Dubois on the orientation of development in bacterial colonies.

*Foreign Doctors Practising in France.*

This question is causing some perturbation among French doctors who return from the war to find their practice absorbed by foreign doctors. These latter are still present in large numbers, especially in Paris and the big towns. The situation was tolerated during the war because the civil population was really short of medical aid; moreover, the intrusion of some of the foreigners was condoned because of services rendered by them to wounded in hospitals. Now, however, the medical societies are moving in the matter and are agitating for the return to the normal interpretation of the laws regulating medical practice in France and requiring the possession of a State diploma as distinguished from that of a university diploma.<sup>1</sup> Many petitions have been sent to the Government by medical men with Spanish or South American or other degrees, claiming exemption from these laws on the grounds of service rendered during the war. On the representation of the Paris medical societies all except 12 of these applications have been refused. The exceptions for the most part have been made for Canadian medical officers of French origin. In the *Bulletin des Syndicats M. le Filiâtre* approves of this exception, and even suggests that it may be extended so as to allow all Canadian doctors to practise in France, assuming that French doctors are granted a reciprocal concession in Canada.

Sept. 8th.

<sup>1</sup> THE LANCET, 1919, i., 477.

## URBAN VITAL STATISTICS.

(Week ended Sept. 6th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.0 in each of the three preceding weeks, rose to 10.7 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 10.5, and was 0.9 per 1000 above that in the preceding week, while among the remaining towns the rates ranged from 4.0 in Swindon, 4.5 in Acton, 4.6 in Enfield, and 4.9 in Coventry, to 14.8 in Plymouth, 14.9 in Gateshead, 17.1 in West Bromwich, and 20.1 in Middlesbrough. The principal epidemic diseases caused 345 deaths, which corresponded to a rate of 1.1 per 1000, and included 251 from infantile diarrhoea, 31 from measles, 30 from diphtheria, 16 from whooping-cough, 13 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 1.2 in Newcastle-on-Tyne, 1.3 in Barrow-in-Furness, and 2.2 in Gateshead. There were 1454 cases of scarlet fever and 1006 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1421 and 1004 respectively at the end of the previous week. The causes of 16 deaths in the 96 towns were uncertified, of which 3 were registered in Liverpool and 3 in Gateshead.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 9.9, 10.7, and 10.9 in the three preceding weeks, fell again to 10.8 per 1000. The 223 deaths in Glasgow corresponded to an annual rate of 10.4, and included 18 from infantile diarrhoea, 4 from whooping-cough, 3 from measles, and 1 from diphtheria. The 78 deaths in Edinburgh were equal to a rate of 12.1, and included 2 each from infantile diarrhoea, scarlet fever, and diphtheria, and 1 from measles.

*Irish Towns.*—The 153 deaths in Dublin corresponded to an annual rate of 19.7, and included 24 from infantile diarrhoea, and 1 each from enteric fever and measles. The 112 deaths in Belfast were equal to a rate of 14.5, and included 12 from infantile diarrhoea, 2 from scarlet fever, and 1 each from enteric fever and diphtheria.

**THE King of the Belgians** has been pleased to grant the *Médaille du Roi Albert* to the following medical men for medical services rendered to Belgian refugees:—

Sir Rickman J. Goilee, Bart., K.C.V.O., Sir Frederick Taylor, Bart., Dr. C. St. Aubyn Farrer, Dr. S. Squire Sprigge, Dr. Chittenden Bridges, Dr. Neville Hart, Dr. J. H. Philpot, Dr. W. E. Robinson, Dr. Arthur C. Roper, Dr. R. M. H. Randell, and Dr. L. Vintras.

**ROYAL INSTITUTE OF PUBLIC HEALTH: TUBERCULOSIS DEPARTMENT.**—A course of lectures for candidates desirous of obtaining positions as tuberculosis officers, for general practitioners and others, will be given in October, November, and December, on successive Thursdays at 5 P.M., beginning Oct. 9th, at the Institute, 37, Russell-square, London, W.C.1. Further particulars can be obtained from the secretaries. The individual lectures will be announced in the Medical Diary.

## Obituary.

THOMAS PICKERING PICK, F.R.C.S.,

LATE VICE-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; INSPECTOR OF ANATOMY FOR ENGLAND AND WALES; CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

WE regret to announce the death, which occurred at Great Bookham, Surrey, on Saturday last, of Mr. Thomas Pickering Pick, the well-known surgeon and anatomist, whose connexion with the Royal College of Surgeons of England for so many years as an examiner made him a familiar figure in educational circles.

A Liverpool man, he came to St. George's Hospital in the days when Prescott Hewett, Timothy Holmes, George Pollock, and the two Lees adorned the staff, and obtained his first diploma in 1862. He held the junior appointments at the hospital, proceeding to the Fellowship of the Royal College of Surgeons of England in 1866. In 1869 he was elected assistant surgeon to the hospital, having previously been an extremely successful demonstrator of anatomy. Indeed, it is as a teacher of anatomy that Pick is always recalled to the memory of his pupils. As a lecturer on his subject he was rapid and correct, but not very inspiring, for he followed the lines of Gray's Anatomy so closely that he was popularly reported among the students to know that elaborate treatise by heart; he was, of course, its most painstaking and capable editor for many years. But as a demonstrator Pick was thoroughly in his element, and he went on demonstrating in an informal way many years after he had become the lecturer on the subject. In talking to a class of students he made the dry bones live, and showed the relations of a dissection in a manner which made the topography of the region for ever a part of the pupil's personal knowledge. For many years he was examiner in anatomy at the Royal College of Surgeons of England, where a dignified presence and a courteous manner concealed to some extent from the students the fact that his standard of exact anatomical knowledge was a very high one. He was possibly responsible for rejections which the disappointed candidate put down to examiners of a less agreeable address. He was at the time of his death Inspector of Anatomy for England and Wales.

In 1879 he became full surgeon to the hospital. He hardly made the same mark as a surgeon or lecturer on surgery that he had made as an anatomist, but his date was decidedly a difficult one. The theory of antiseptics was universally accepted, but only after discussions in which many of Pick's immediate superiors were not found on the progressive side; while the technique of what in the early eighties was still regarded as a completely new thing, called for much perfecting. Pick was not quite flexible enough to assimilate the Listerian doctrine, nor had he a sufficiently scientific outlook to enable him to see its tremendous promises. He remained the absolutely capable surgeon of his time, conforming to the antiseptic creed, but unable to forget that only a few years ago he had passed successfully tests in his professional subjects without requiring any knowledge of germ influence. He wrote, however, a good little treatise on fractures and dislocations, exclusive of fractures of the skull, as well as a treatise on surgery for practitioners. Each book was the outcome of personal experience, as well as a record of the principles of surgery as he had learnt them and practised them. He also edited Holmes's "Principles and Practice of Surgery," which was for many years one of the most popular manuals with English and American students. The handbook, however, was not kept up to date, and, indeed, the years when Pick was its editor were so marked with surgical developments that the work would have required almost annual re-issue if it was not to fall behind, as well as steady collaboration with younger men.

Pick's connexion with the Royal College of Surgeons of England was a long and honourable one, though he failed to be elected President. Appointed to the Board of Examiners in Anatomy and Physiology in 1876, he continued to be a member of the Court of Examiners until 1894. In this year, as Hunterian Professor, he delivered at the College an interesting series of lectures on Diseases of the Ends of the Long Bones in Children, which were published in these columns, and display their author as a sound surgeon

with a great knowledge of pediatrics. In 1898 he delivered the Bradshaw lecture, taking as his subject the Union of Wounds, and in 1903 he became Vice-President of the College. No doubt the failure to be elected President of the Corporation for which he had worked so long and loyally was a great disappointment to him.

ALEXANDER MACALISTER, M.A., M.D. CAMB., M.D., D.SC. DUB., LL.D. GLASG., MONTREAL, & EDIN., F.R.S.,  
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF CAMBRIDGE.

By the death of Alexander Macalister Cambridge loses one of her most ardent spirits and devoted servants, for though he had been educated elsewhere and had made his reputation before he migrated, no one of her sons was more loyal than was Macalister to the home of his adoption, or brought to bear on the duties of the professoriate a wider and riper experience of men and affairs. Looking back on the many and prominent parts he played, it can be realised how profound and beneficial has been his influence in the moulding of the character and work of his pupils.

Alexander Macalister was born in Dublin in 1844, the second son of Robert Macalister, and grandson, on his mother's side, of Colonel James Boyle of Dungiven. Educated at Trinity College, Dublin, he took his first medical qualification in 1862, and became in succession demonstrator of anatomy at the College of Surgeons, and professor of zoology, and then of anatomy and chirurgery in the University of Dublin. During this period he published an introduction to "Animal Morphology" (1876) and the "Morphology of Vertebrate Animals" (1878), and entered very fully into the life of the University, becoming a member of the Senate.

Macalister came to Cambridge in 1883 in that great period of evolution—almost of revolution—inaugurated by Coult's-Trotter, Humphry, George Paget, Michael Foster, and Latham, their survivor—men who, though not always pulling together, launched a new and vigorous medical school on the main stream of comparative anatomy, embryology, and physiology. Succeeding Sir George Humphry, Macalister had assigned to him the task of reorganising the work of the department of anatomy and of remodelling the teaching of his subject. How far he succeeded in adapting modern scientific teaching and methods to the requirements of the university is now a matter of history; for though it is sometimes maintained that his teaching was not sufficiently "surgical" to meet the requirements of the student of medicine, he built up a department that, ample enough at the time it was planned, is already inadequate to the demands made upon its resources and accommodation. It may be that if the passing of professional examinations outside the university by his pupils be made the stand of his success it was not so complete as was that of some, but if the thorough grounding of men in the principles of anatomy be taken as the test, his was the more solid and lasting education. Macalister's exceptional powers and abilities could never have found sufficient outlet in any single branch of anatomical investigation and teaching; archæology, craniology, and comparative anatomy all claimed a share of his energies, his attention to detail and marvellous thoroughness ensuring the success of his researches in all these fields, whilst the same attention to detail, the wealth of illustration he always had at command, his directness and independence of thought, combined with his devotion to the interests of his pupils, rendered his teaching not instructive merely but intensely stimulating and highly suggestive. Only those who know how willingly and lavishly he gave of his time and strength to the advancement of his subject and in the training of those working under him on broad scientific lines can have any idea of the success of his teaching, and how sorely colleagues and students, young and old, will miss the quiet persuasive manner, calm, well-balanced judgment, wide, almost encyclopædic, but profound, knowledge, and dry humour that characterised his dealings with them. His deep religious feeling and acute moral sense account for the keen interest he took in missionary work and the call to which he responded so joyously to visit the Far East, there to advise, help, and encourage those labouring in the China mission-field. One of the most highly equipped of our intellectuals he was modesty and humility personified in his respect for the opinions of others and in his attitude

towards religion, which with him was no superficial thing, but was woven into the very web of his being, animating, guiding, and controlling his whole scheme of life.

One of his old demonstrators (E. R. T. C.) writes: "Macalister was an outstanding example of a man officially associated with the exposition of one subject (human anatomy), but capable, in virtue both of his intellectual powers and actual knowledge, of assuming an equally eminent position to any of several other spheres of learning (zoology, philosophy, archæology). From all these provinces of thought Macalister drew deeply wherewith to enrich, to exemplify, and to integrate his teaching of human anatomy. His draughtsmanship was inimitable, and his execrancy as a dissector that of a master craftsman, most excellent to witness. Many old Cambridge students will regretfully miss the kindly reminiscent welcome which was theirs when, on rare visits, they looked in at 'the Rooms.'"

Professor Macalister married a daughter of James Stewart, of Perth, who predeceased him. He leaves two daughters, one of whom is the wife of Sir Donald MacAlister, and a son, Dr. R. A. S. Macalister, who is professor of Celtic archæology in Dublin. G. S. W.

ARCHIBALD HENRY HOGARTH, M.A., M.D. OXON., D.P.H.,

MEDICAL OFFICER OF HEALTH FOR BUCKINGHAMSHIRE.

THE death of Dr. A. H. Hogarth at Quainton on Sept. 5th, in his 42nd year, leaves a gap in the Public Health Service which it will be difficult to fill.

Archibald Henry Hogarth was educated at Westminster School and Christ Church, Oxford, where he graduated in 1901. Going on to St. Bartholomew's Hospital, he obtained the Conjoint qualification in 1903, and the M.B., B.Ch. Oxon. in the following year. He then acted for some time as assistant medical officer to the Port of London, where the housing problems could hardly fail to arrest the attention of a man of his bent, and his first considerable contributions to social medicine were in the form of comprehensive reports to the Mansion House Council on Health and Housing, to which for some time he acted as secretary. Leaving the Port and its sanitary problems to join the educational staff of the London County Council, Hogarth met the second great pre-occupation of his busy life, and set to work to establish legislation on school hygiene, his pioneer book on "Medical Inspection of Schools" (1909), which had a wide circulation, doing much to form public opinion. He then became the first medical officer of health for the county of Buckingham, where he had special care for all health matters throughout the countryside, particularly in attention to dental care for children, to infancy and maternity nursing, and later to schemes for venereal disease control.

Whilst an Oxford undergraduate Hogarth served through the Boer War with his regiment, the Queen's Own Oxfordshire Hussars, and gained the D.C.M. On the outbreak of the recent war he rejoined his regiment and went to France as regimental surgeon, and after the armistice he was again sent out, this time by the Air Ministry, on a special mission to the Eastern Mediterranean, where he worked among the influenza-stricken camps in the Levant. On his return voyage an attack of Vincent's angina lowered a constitution at no time robust, and he never regained his strength.

Hogarth was a tremendous worker and inspired with something of his own zeal those who worked with him. No one who saw the organisation of public health work in Buckinghamshire could have guessed that its organiser was living in London and riding most of his old hobbies there. Whatever he was at, he collected his information and examined questions with thorough and scientific method; he had a great contempt for all shams or pretence, and, drawing his own conclusions, went forward in a strenuous and impetuous way. He thus accomplished much and always, whether in peace or war, fought the good fight. His writings resembled his actions, and from the time when he edited his hospital journal to his latest works on administrative health problems, the same eager note was characteristic of them and a freshness which his official position did nothing to spoil.

Of Hogarth's attitude to public health administration something should be said, for he breathed a spirit in which generous rivalry flourished while controversy faded. A whole-time officer himself, he fully recognised the claims of part-time service. He saw that reconstruction of medical work

in rural areas must be to a large extent organised on a part-time basis. The likely solution of efficient rural hygiene was not to him the parcelling out of the country into areas conveniently worked by whole-time officers on Whitehall lines, but rather a happy combination of part-time medical service under local sanitary committees, with administrative control by whole-time county council officials. In a memorandum which he drew up for the Labour Party's Advisory Committee on Public Health, he proposed the delegation by county and county borough councils of their powers and duties to six statutory committees, dealing respectively with asylums and mental deficiency; sanitation and housing; maternity and child welfare; industry, social welfare, and pensions; sanatoriums and hospitals; insurance and domiciliary treatment; each with the duty laid upon it of appointing an independent and responsible whole-time medical officer. It is lamentable that death should have prevented him seeing the further working-out of this attractive scheme in his own county, where already the Public Health and Insurance Committees were acting in complete unison.

Dr. Hogarth married Margaret MacDonald, M.B. Aberd., formerly London County Council medical inspector of schools, and leaves one son.

FREDERICK WALTER LOWNDES, M.R.C.S. ENG., L.S.A.,  
CONSULTING SURGEON, LIVERPOOL LOCK HOSPITAL.

WE regret to announce the death of Mr. Frederick Walter Lowndes at the advanced age of 81. Born in Liverpool, where his family had for many years held a prominent position, Lowndes spent his whole life in the city of his birth, working hard there as doctor, philanthropist, and official. He did not intend in the first instance to adopt a medical career, but at the age of 23 he gave up a clerkship in a commercial house and went to Edinburgh to study what he rightly felt to be his vocation. In 1865, having obtained his qualifications, he returned to his native city to practise, and during the greater part of his early career he was frankly a poor man's doctor. The experience which he thus gained, as well as the insight which he obtained of the exact way in which the poor live, made him a zealous worker for all medical charities, and especially was he one of the earliest champions of the Hospital Sunday Fund. In this connexion he became the close ally of Dr. James Wakley, at that time Editor of THE LANCET and one of the founders of the Fund, and the result of their meeting was that Lowndes became for a long period of years a member of the editorial staff of this paper. In our columns and in those of the *Liverpool Courier* he wrote many forcible articles on the position of the voluntary hospitals, and the need for concerted effort among the public in support of these charities unless their voluntary character was to be exchanged for the position of the rate-aided institutions.

Other questions of a medico-public nature in which he was particularly interested were burial reform and the medical conduct of inquests. A pamphlet which he wrote setting out the reasons why the office of coroner should be held by a member of the medical profession ran through several editions, and is an admirable piece of pleading. But Lowndes was not a bigot in his views. He held that the appointment of coroner rightly belonged to his profession because the medical element in the evidence, so frequently the most important one, was very hard for a layman to explain to a lay jury; but he always granted that the lawyer's method of procedure might smooth the course of justice. And he had considerable legal knowledge. He was for many years medical officer to the Liverpool Constabulary, gave evidence in various important trials, and had an intimate acquaintance with criminology. He was a walking encyclopædia of information concerning famous cases.

DR. G. A. BATCHELOR, OF PRETORIA.—Dr. George Arthur Batchelor, Government district surgeon, of Rayton, Transvaal, who recently died at Pretoria Hospital, was born in India 64 years ago. He studied medicine at Aberdeen and the London Hospital, taking the M.R.C.S. in 1877, the M.B., C.M. Aberd. in 1879, and M.D. in 1895. He also took a D.P.H. and was awarded the M.D. Cape University. Before settling in the Transvaal he practised for a time at Cradock, Burgersdorp, Alwal North, and Sea Point, in Cape Colony. He leaves a son of the same name in practice at Dogies, Transvaal.

## Correspondence.

"Audi alteram partem."

### THE UNIFICATION OF THE ARMY MEDICAL SERVICE AND ITS RELATION TO "TEAM PRACTICE" IN CIVIL LIFE.

To the Editor of THE LANCET.

SIR,—When I entered the A.M.S. some 53 years ago it represented individual and personal practice in a very definite way, and "team practice," as the coöperation of medical men is now called, was practically unknown. The unification of the A.M.S., which I helped to achieve, is a definite model to-day of "team practice," but no doubt much remains to be done to tighten the bonds of the unification idea. Thirty years of stress and strain will pave the way to better conditions, and in 1949 the civil medical profession will have taken definite form as a "team" organisation. To-day we have made the physician a tradesman selling cures; in 1949 he will be a scientific official guarding life. Army medical unification was not achieved even in its present incomplete condition without personal discomfort and at times actual suffering, hence the need of care and anxious study and investigation of proposed schemes of medical reform.

The primary function of the State in helping on medical unity will be the provision of increased local educational facilities, brought to the very thresholds of the medical men of the new era. Large sums of money will be needed to achieve this end, and not a farthing of the money will go to the individual medical man as a bribe or *personal* benefit. A central library, a central laboratory, facilities to spread broadcast the diplomas in public health, and leave of absence for rest and leisure guaranteed by the State, together with sick leave with State pay in case of illness—by these tempting boons we may draw into "union" the highly individualised medical profession of to-day. Grants in aid for retiring pensions will gradually creep in, and age retirement with pension may follow on our Army lines. The central municipal dispensary, selling medicine at cost price, will no doubt be a feature in the new organisation of public health in its wisest sense, and that boon will relieve many anxieties that exist to-day in private practice. The presence of State-paid "district consultants," who will be available for consultative work at quite moderate fees to patients, will gradually appear, and any interferences with the routine of private practice by these consultants will be forbidden by definite rules.

Just as we grant forage and horse allowance to medical officers in large districts, so grants in aid for the transport of the medical man will be quite usual. The life of the medical student and his facilities for complete study will be aided in a degree to-day undreamed of, and this alone would be a real boon. The wretchedly defective literary and scientific examination that admits badly educated men into colleges as medical students will be sure to be dealt with, and a General Medical Council full of progressive ideas will replace the antiquated machine which now blocks the pathway of progress.

The reforms to be made will creep on with such almost imperceptible steps that it will appear as if nothing was doing, but at the end of every decade progress will be completely visible, and in a generation victory will be evident. During the whole of these years of stress and strain that are to come men will appear who "want all at once." Such men appear in all movements of progress, but they have to be borne with, and eventually they find their place in the column of march. What makes me sad is that splendid men with whom I worked, the latchet of whose shoes I was unworthy to let loose, and who hoped and dreamed of progress in all its splendour, perished by the roadside and never even saw the Promised Land. When I think of these splendid men, who never lived into the sunshine, then, indeed, I feel regret. Civil reformers will have to endure the same sorrows and will have to hope for the same joys of success.

I say now, as I said to others then, "Fight the good fight; victory is sure to come." The man, the woman, and the child, constituting as they do "the Trinity of Humanity," will surely come into their own as civilisation advances. The pity of it all is that Edmund Parkes, with his beautiful face,

charming ways, and splendid science, is no longer with us; that Florence Nightingale, a veritable tower of strength in health matters, and hidden and concealed by her nurse's dress, has "gone West"; that Sir William Muir, the lion of unification, is at rest; that William Johnston, the brilliant organiser who looked down into the valley of unification but never sat by the waters and rested—all these have passed away. We must never forget the names of these brilliant workers in the new work that is now coming on.

I am, Sir, yours faithfully,

GEORGE EVATT, M.D.,  
Major-General (retired), A.M.S.

Junior United Service Club, London, Sept. 8th, 1919.

## CRYPTOPODIA—DIFFUSE FIBROMATA OF THE FEET.

To the Editor of THE LANCET.

SIR,—On Oct. 2nd, 1906, I made an exploratory incision into the dorsum of a child's foot, which was the seat of a condition probably similar to that of Dr. E. C. Bousfield's patient, described in THE LANCET of August 23rd last. The following are the brief notes of the case, written at the time:—

R. H., aged 15 months, had a diffuse symmetrical fibroma on the whole of the dorsum of each foot. The condition was congenital, but the swellings had grown and formed large pads which overhung the toes. Another child of the same parents, and now aged 3 years, has one foot similarly affected, and these two are the only children of the family. An incision was made into the dorsum of one foot, and showed dense smooth fibrous tissue, from which oozed much clear fluid. The fibrous layer of the skin was continuous with the tumour (i.e., there was no subcutaneous fat). An X ray examination showed the bones of the feet to be normal, and a microscopic examination of a piece of the tissue removed showed it to be composed of fibrous tissue containing blood-vessels with thickened walls.

I know nothing of the subsequent history of the children, and I have seen no other case like it.

I am, Sir, yours faithfully,

WM. ROBINSON, M.S., F.R.C.S. Eng.,  
Sept. 6th, 1919. Senior Surgeon, Royal Infirmary, Sunderland.

## THE TERRITORIAL FORCE MEDICAL OFFICERS' ASSOCIATION.

To the Editor of THE LANCET.

SIR,—As it is not possible to send notices to individual officers, I shall be obliged if you will allow me to announce in THE LANCET that the dinner of the Territorial Force Medical Officers' Association will take place on Thursday, Oct. 30th, at 7.30 P.M., at the Holborn Restaurant.

The charge for tickets is 12s. 6d., not including wine. All Territorial medical officers can attend and bring guests. Application for tickets should be made to me at this address, the office of the association.—I am, Sir, yours faithfully,

D. L. HAMILTON,  
Lieutenant-Colonel, Honorary Secretary.  
37, Russell-square, London, W.C.1, Sept. 8th, 1919.

## ANTIVIVISECTION SHOPS.

To the Editor of THE LANCET.

SIR,—One of the antivivisection societies lately opened a shop, for three weeks, in Oxford, and will probably open it elsewhere, moving it from place to place. There were many of these shops in the years before the war, and I shall be grateful if anybody in whose neighbourhood the shop appears will immediately let me know of it, so that arrangements may be made for the distribution of leaflets to counteract its influences.

I am, Sir, yours faithfully,

STEPHEN PAGET,  
Hon. Sec., Research Defence Society.  
11, Chandos-street, Cavendish-square, London, W.1,  
Sept. 8th, 1919.

## INDUSTRIAL WELFARE WORK.

To the Editor of THE LANCET.

SIR,—During the last three years, inspired by the efforts of far-seeing firms, the welfare movement has made very rapid strides in this country, and the wide recognition now being given to it by employers, workers, and public men

leaves little doubt but that within a few years it will occupy a very prominent position in the industrial world. So far no real attempt has been made either by State or voluntary agencies to collate information regarding various phases of the work; in fact, the names of firms interested in the movement are not even recorded in any place. The Industrial Welfare Society is anxious, for the benefit of industry generally, to collect from the pioneers of this movement information regarding their doings in connexion with welfare work. I shall therefore be grateful if those firms who are willing to assist in this way will apply for particulars of the information desired to the Industrial Welfare Society, 33, Tothill-street, Westminster, S.W.1.

I am, Sir, yours faithfully,

ROBERT R. HYDE,  
Director.  
Sept. 9th, 1919.

## KERATODERMIA BLENNORRHAGICA.

To the Editor of THE LANCET.

SIR,—The case recorded by Dr. S. C. Dyke in THE LANCET of August 23rd presents points of great interest. Keratoderma blennorrhagica is generally considered a somewhat rare disease, having been first described in 1893 by Vidal and first in England by Sequeira<sup>1</sup> in 1910. Possibly cases would be more often observed, as McDonagh<sup>2</sup> suggests, if the soles of the feet were examined in all cases of gonorrhoea—for he says that three cases a year are seen at the London Lock Hospital. Histologically, the growth resembles gonorrhoeal warts. It is thought that the gonococcus possibly invades the skin, and in support of this view the case recorded by Dr. W. E. M. Armstrong in THE LANCET of May 17th, 1913, is of interest. Here wart-like growths appeared on the face in a man who had before previously an acute conjunctivitis secondary to gonorrhoea. The secretion had overflowed on to his cheeks, and he had also rubbed them to improve his colour, as he thought he looked pale. This condition, as in Dr. Dyke's case, was rapidly cured by vaccines. Further, Armstrong determined the opsonic index of the blood for the gonococcus before and after inducing congestion in the face, and found a swing indicating an active gonococcal infection. Keratoderma plantæ is known to be associated with niritis in cases of arsenic poisoning; gonorrhoea may cause peripheral neuritis, the sciatic nerve being most often affected.

These cases are probably due to the gonotoxin and not to direct invasion by the gonococcus. It would be interesting to know whether there were signs of peripheral neuritis in Dr. Dyke's case, for if so possibly keratoderma blennorrhagica may fall into line with arsenical keratoderma, and both be secondary to a toxic neuritis affecting especially the trophic nerves of the skin.

I am, Sir, yours faithfully,

Avonmore-road, W., Sept. 1st, 1919. G. E. BEAUMONT.

<sup>1</sup> Sequeira: Brit. Journ. of Dermatology, 1910, p. 139.

<sup>2</sup> McDonagh: Biol. and Treatment of Venereal Diseases, 1915.

VITAL STATISTICS OF SCOTLAND.—A remarkably high marriage-rate, together with low birth- and death-rates form the most notable features of the statistics published for Scotland for the second quarter of the year 1919. The marriage-rate, 9.5, is the highest quarterly rate on record, while the birth- and death-rates are the lowest recorded for the corresponding quarter of any year.

NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY.—A course of elementary lectures on infant care, for teachers, infant welfare workers, and others, will be held at 1, Wimpole-street, London, W., on Mondays, 5.30 to 6.30 P.M., from Sept. 29th to Dec. 15th inclusive, in preparation for the elementary certificate of the association. The examination is open to all students who attend eight or more out of the 12 lectures. The fee for the whole course is 5s.—A course of elementary lectures on infant care, especially intended for creche nurses and probationers, will be held at the Essex Hall, Essex-street, London, W.C., on Thursdays, 7.30 to 8.30 P.M., from Sept. 25th to Dec. 11th, inclusive, in preparation for the Creche Nurses' Certificate, now instituted by the Association and the National Society of Day Nurseries. The fee for this course is 10s.—Tickets for either course can be obtained from Miss Halford, Secretary, National Association for the Prevention of Infant Mortality, 4, Tavistock-square, London, W.C.1.

## The Services.

### R.A.M.C. TEMPORARY OFFICERS.

THE War Office is prepared to accept the services of medical practitioners, including those who have been demobilised, who are desirous of undertaking duty with the Army.

Candidates who have served before will be commissioned in their previous rank. Lieutenants who have completed one year's satisfactory service as such will be commissioned as Captains. Those who have not served previously will be commissioned as Lieutenants.

The period of engagement will be for six months, and the contract will not be terminable by either party prior to the expiration of that period, except for misconduct, inefficiency, or medical unfitness.

Pay to be at the rate of—Lieutenants £600 per annum, Captains £650 per annum, and in addition the following will be issuable:—

(1) Pay at the rate of £50 per annum when serving elsewhere than in Europe.

(2) Rations or an allowance in lieu thereof (present rate 2s. 1d. per diem).

(3) Specialist's, or charge pay, when holding a position for which the issue of such is authorised.

(4) Officers holding higher acting or substantive rank than that of Captain will, if desirous, be granted the pay and allowances of their rank.

Kit and outfit allowance will be issued to candidates who have not previously received such allowance.

All candidates must be fit for general service or garrison duty abroad, and will require to undergo a medical examination prior to being accepted.

Applications should be addressed to the Secretary, War Office, Cornwall House, Stamford-street, London, S.E. 1.

The King has approved the relinquishment of temporary rank in the Indian Medical Service and Indian Defence Force by Capt. Villupuram Rajaratna Nateson.

## Medical News.

WE call the attention of our readers to a letter on p. 502 from Mr. Stephen Paget, the honorary secretary of the Research Defence Society. Mr. Paget asks for early warning as to the opening of antivivisection shops, so that he may counteract, through the Research Defence Society, the mischievous misrepresentations to which these places give concrete form.

Dr. John Cahill, who died on Saturday last, was a member of the Egyptian Government Medical Commission, and during the war had been acting as assistant physician to St. George's Hospital.

Dr. Charles Cameron Slorach, of Dumbarton, was killed last week in the Mount Vernon district, near Glasgow, through the motor-car in which he was riding coming into collision with a traction engine. His wife and son, who accompanied him, were injured.

THE St. Thomas's Hospital Old Students' dinner will take place at the Connaught Rooms, Great Queen-street, W.C., on Wednesday, Oct. 1st, at 7 o'clock for 7.30. The chair will be taken by Sir George Makins, President of the Royal College of Surgeons of England.

THE LUNACY BOARD OF CONTROL: FIFTH ANNUAL REPORT.—The report shows a continued decrease in the number of notified persons under care in England and Wales. The total was, last New Year's day, 116,703, and the actual decrease from year to year: 1918-19, 9138; 1917-18, 8188; 1916-17, 3159. In the 80 asylums which continued to receive patients throughout the year the death-rate was: males 25.2 per cent., and females 16.4 per cent., being a further increase of 3.7 and 2.4 per cent. respectively on the high mortality of the previous year, and attributed in the main to influenza and tuberculosis. 6577 mental defectives were resident in certified institutions. The total expenditure for the year on the upkeep of county and borough asylums was £4,062,752, being an increase on the year of £295,717. The average weekly cost of maintenance per head was 14s. 5d., a rise of 1s. 9d. on the cost of the previous year.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students of the hospital will be held at the Connaught Rooms, Great Queen-street, W.C., on Saturday, Nov. 22nd, at 7 P.M., Sir Harry Baldwin in the chair. This being the first post-war reunion, it is hoped a large number of those interested will find it convenient to be present.

FAILURE OF LONDONDERRY WATER-SUPPLY.—An Irish Correspondent writes: The authorities of such an old and important Irish city as Londonderry cannot be congratulated that, owing to their continued procrastination, the water-supply has practically failed. On Sept. 2nd bakeries were carried on with difficulty, picture-houses had to be closed, and no public and only two private houses had electric light. The citizens have been warned to use what remains of the water-supply only for cooking and washing, as it is now in their hands to prevent a famine. On Sept. 2nd the thousands of shipyard and factory workers who turned out in the morning as usual for work had to be sent home again because it was discovered that no water was coming into the tanks at the electric station from the reservoir from which the station draws its supply, with the result that the shipyard engineer had no other alternative but to cut off the supply to the industries, as there was an absence of electric power. A gallon of water per head each day would enable the engineer to provide the necessary power. Until the corporation make up their minds what is to be done in the serious crisis that has arisen, all supplies of water for industrial and business purposes are discontinued, and establishments found using water are to be prosecuted. A similar crisis arose in 1911 in Londonderry, but in the interval the population has increased by 8000, and the shipyard has to be considered. At a meeting of the corporation on Sept. 4th a deplorable situation, as regards the water-supply, was revealed by the city engineer, who said that "if they kept the water they had for domestic purposes only, they could maintain about five weeks' supply at the very outside, provided the citizens exercised the most rigid economy and used only the very minimum." He was prepared to supply the electric station with the necessary water (to begin on Sept. 8th) to enable the necessary power to be provided to carry on industry, although he would be taking considerable risks in doing so, but he could not supply water for trade purposes or for laundries, and he could only give water to factories for sanitary purposes, and even that could not be guaranteed at any particular time; and on the above recited conditions he was prepared to resume a ten days' trial of supplying water for electric power. No wonder the daily press regard such a condition of affairs as a grave crisis for an old city whose population at the last census was 40,779. In Belfast, as reported on Sept. 4th to a meeting of the Water Commissioners, the water in store on August 28th was 1103 million gallons, which is 501 million gallons less than the quantity in store on the corresponding date of 1918. The city has been put on a diminished supply, none flowing into the cisterns at night, a practice of little use, as people simply fill their baths and other receptacles during the day. Unless rain comes in large quantity a serious crisis may also arise in Belfast from the deficient water-supply.

## Appointments.

CHISHOLM, JOHN, M.B., Ch.B. Edin., has been appointed Registrar to the Jessop Hospital for Women, Sheffield.

Sussex Throat and Ear Hospital: HUTCHISON, A. J., Honorary Consulting Surgeon; RIGBY, MORRIS, and CROW, DOUGLAS A., Assistant Honorary Surgeons.

## Births, Marriages, and Deaths.

### BIRTHS.

DICKINSON.—On Sept. 6th, at Newcastle-upon-Tyne, the wife of W. H. Dickinson, M.B., D.P.H., of a son.

FULLER.—On Sept. 4th, at Priory Cottage, Freshwater, I.W., the wife of Capt. R. Annesley Fuller, M.C., R.A.M.C., of a son.

MACALPINE.—On Sept. 10th, at Cranbrook, Prestwich, Manchester, the wife of Jas. B. Macalpine, F.R.C.S., of a daughter.

### MARRIAGES.

DUNN—JACKSON.—On Sept. 3rd, at St. James' Church, Edgbaston, Major Naughton Dunn, R.A.M.C., to Ethel Violet, daughter of Mr. and Mrs. George Jackson, of Glewstone Court, Herefordshire.

PHILLIPS—MORGAN.—On Sept. 9th, in London, Hugh Richard Phillips, M.D., of 2, Cavendish Court, Cavendish-square, to Phyllis Morgan.

### DEATHS.

CAHILL.—On Sept. 6th, at Pinkneys Lodge, Pinkneys Green, the residence of his brother-in-law, Mr. Stanley Keith, John Cahill, M.D., F.R.C.S. Eng., of Seville-street, Lowndes-square, S.W., aged 62.

PICK.—On Sept. 6th, at The Nook, Great Bookham, Surrey, Thomas Pickering Pick, F.R.C.S., consulting surgeon to St. George's Hospital, London.

N.B.—A fee of 6s. 4s. charged for the insertion of Notices of Births, Marriages, and Deaths.

LAST week an announcement appeared in this column of the marriage of Captain W. E. Elliot, M.C., R.A.M.C., Member of Parliament for Lanark, and Miss Helen Jamfion. The tragic sequel has been widely noted in the daily press. Mrs. Elliot fell some hundreds of feet while mountaineering in Skye, dragging her husband down with her. She was killed on the spot and Captain Elliot somewhat severely injured.

## Medical Diary for the ensuing Week.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton and others:—

WEDNESDAY, Sept. 17th.—4.30 P.M., Lecture XIII.—Aetiology and Pathology of Carcinoma and Sarcoma of the Stomach.

FRIDAY.—4.30 P.M., Lecture XIV.—Symptoms and Treatment of Carcinoma and Sarcoma of the Stomach.

### Communications, Letters, &c., to the Editor have been received from—

A.—Dr. F. P. Atkinson, Bexhill-on-Sea.

B.—Messrs. J. Bibby and Sons, Liverpool; British Red Cross Society, Lond.; British Association for the Advancement of Science, Lond.; Mrs. C. Brereton, Lond.; Dr. A. Balfour, C.M.G., Lond.; Sir John Bland-Sutton, Lond.; Col. E. J. Blackham; Mr. C. K. Bond, Brighton; Prof. D. T. Barry, Cork; Dr. G. Blacker, Lond.

## Notes, Short Comments, and Answers to Correspondents.

### PLAGUE AND INFLUENZA IN INDIA.

FOR more than half a century the Government of India have issued annually a Blue-book entitled "Statement Exhibiting the Moral and Material Progress and Condition of India." The fifty-fourth of these statements, dealing with the year 1917-18, has recently been presented to Parliament, and included in its various contents are the following remarks on local self-government tested by disease and scarcity:—

As a symptom of the vitality of the institutions of local self-government in India, it may be mentioned that they rendered excellent service in seconding the efforts of the central and provincial governments in grappling with two of the most important administrative problems which occurred during the period under review—namely, the incidence of epidemics and the high prices of commodities.

#### Plague.

The monsoon of 1917 was exceptionally abundant and, partly perhaps in consequence of this, plague made its appearance in serious degree during the year. Between July, 1917, and June, 1918, the total number of deaths from plague was over 800,000. Although, fortunately, there is reason to believe that the incidence of the disease in India is on the wane, the distress and dislocation caused by this mortality was very great. In addition to the influence of the plague epidemic the year as a whole was very unhealthy, and a high death-rate occurred both from cholera and malaria. Relief measures were undertaken by the local administrations, the provincial sanitary and medical officers laboured with the utmost zeal, and the number of hospitals and travelling dispensaries was everywhere increased. Preventive measures in the way of evacuation of infected areas were undertaken in many places, and inoculations were carried out on a larger scale than was previously known.

#### Influenza.

Bad as were the general conditions of public health in India during the year 1917, those of 1918 were infinitely worse. In the month of June, 1918, came the first intimation that influenza in a virulent form was attacking India. In the city of Bombay towards the end of that month many employees of offices, banks, and so forth were incapacitated by fever. The disease began to spread over India, and before long the mortality, at first low, began to rise in an alarming degree. In the city of Bombay itself the mortality reached its maximum on Oct. 6th, on which day 768 deaths were recorded. The full force of the outbreak was felt by the central, northern, and western portions of India, in comparison with which Bengal, Burma, Bihar, and Orissa, Madras, and Assam suffered but lightly. During the last quarter of 1918 India seemed to have suffered more severely than any other country in the world; and influenza was responsible in British India alone for a death roll of approximately 5 millions. Detailed information with regard to the incidence of the disease in the Indian States is not available, but it is unlikely that the influenza mortality therein fell short of 1 million. Within the space of four or five months influenza was thus responsible for the deaths of 2 per cent. of the total population of British India. In some places—the Central Provinces for example—two months of influenza caused twice as many deaths as 22 years of plague. In Bombay, between Sept. 10th and Nov. 10th, the total average mortality was 326 deaths a day. Had mortality continued at this rate throughout the year the death-rate of the country would have been over 120 per 1000 of the Census population. The Punjab also suffered very severely.

#### Efforts to Cope with the Disease.

The provincial administrations and the local bodies to whom is mainly entrusted the maintenance of sanitation and public health made whole-hearted endeavours to ameliorate the sickness and suffering occasioned by the outbreak. The epidemic struck India at a time when she was least prepared to cope with a calamity of such magnitude. War demands had depleted her sanitary and medical personnel, which at best is inadequate when considered in relation to the size of her population and of the tenacity with which the population clings to domestic customs injurious to public health. The overworked staff that remained was struck down in large numbers. Still more serious were the effects of the almost total failure of the monsoon, which exercised a disastrous influence practically throughout the country. The staple food grains were at famine prices, and the scarcity of fodder reduced the quantity of milk available. Although there is no reason to suppose that the epidemic originated in malnutrition, it was particularly unfortunate that the price of nourishing food, and also of such comforts as blankets and warm clothing was extremely high. In all the larger towns, where severe epidemics occurred, many additional dispensaries were opened by the local authorities, and numerous agencies were employed for the free distribution of drugs and milk. In some towns municipal grain shops were opened which supplied grain below the market rates. Endeavours were made by all administrations to instruct the people as to the nature of the malady, as to measures for its prevention, and as to measures to be adopted when it had set in. The efforts of official bodies, whether provincial or local, were nobly seconded by non-officials, by philanthropic societies, by educational establishments, and by a host of voluntary workers. Everything that could have been done with the agency available was done. But with a population as vast as is that of India to-day, with a relatively low standard of living, the control of so virulent an epidemic is completely outside the present scope of human endeavours.

The magnitude of the task which the administration was called upon to face may be gauged from the fact that, according to the report, it has been estimated that from 50 to 80 per cent. of the total population

of India has recently suffered from influenza. It is undeniable that the catastrophe was rendered more complete by the generally insanitary conditions under which the major portion of the population of India live their lives; and the necessity of redoubling the efforts of the administration, both central and provincial, to secure the improvement of those conditions, has become more than ever apparent.

### MEDICAL WOMEN IN CONFERENCE ON SOCIAL PROBLEMS.

AN International Conference of Women Physicians, promoted by the War Work Council of the Y.W.C.A., is to be opened in New York on Sept. 15th, and will sit for six weeks. Some 30 representative medical women from various parts of Europe have accepted the invitation to the Conference; doctors from India and China, South America and Canada, are also expected, and delegates from the United States themselves will doubtless be numerous. The general purpose is to learn the attitude towards social education in health and sex problems taken up by the various countries of the more or less civilised world, and to discuss individual national problems. After the more technical aspects of these problems have been dealt with by the Conference, selected members of the lay public will be invited to join the medical women during the last week of their session. The object of this general conference will be to reach a common ground of understanding upon which to base coöperative methods in dealing with social problems affecting the women of the world. The tentative programme submitted to us suggests that the proceedings of this gathering are likely to be of great interest.

### THE ETHICS OF ADVERTISING.

AN editorial article in the *Journal of the American Medical Association* of August 9th contains some shrewd remarks on this subject. What is there about advertising having a medical "slant" that so often causes the advertiser to abandon the principle of honesty and common sense? Products which are sufficiently good to stand on their own merits and which, when advertised in a non-medical way, are described truthfully, when they enter the medical or quasimedical field are presented to the public in such a way as to cast discredit on the whole field of advertising. "These thoughts are provoked," says our contemporary, "by an advertisement that has recently appeared in certain medical journals on 'Adams Chewing Gum.' The product itself is one that certainly needs no misstatements or quibbling to stimulate its sale. The advertisement in question is entitled 'The Care of the Mouth,' and is made up largely of what purports to be a quotation from an article by a 'pediatrician.' There are two things wrong with the advertisement. First, the reader is given the impression that the quoted article has appeared comparatively recently; it appeared about eight years ago. Second, the quotation has been garbled and the writer is made to say things that he never said. The parallel indicates the liberties that have been taken:

#### Original Article.

'The child naturally rebels against THE CLEANSING PROCESS while it is VERY ill and therefore if some more attractive and efficient way can be found to accomplish the same result, we ought to take advantage of it. THE USE OF CHEWING GUM seems to offer the best relief. It is attractive to the child .....,' etc.

#### As Quoted in Advertisement.

'A child naturally rebels against MOUTH cleansing while it is ill or peevish, and therefore if some more attractive and efficient way can be found to accomplish the same result, we ought to take advantage of it. 'ADAMS PEPIN CHEWING GUM seems to offer the best relief. It is attractive to the child .....,' etc.

The portions that fail to coincide have been put in small capitals. Aside, altogether, from the medical aspects of the case, and aside from the morality or ethics of the matter, the liberties which the Adams Chewing Gum concern have taken with the article have weakened rather than strengthened the 'copy.' These advertisements were for medical journals. The average physician, in reading the advertisement as it appeared, would immediately have his suspicion aroused. This in itself is bad advertising. The reader, knowing that the average physician does not, in scientific articles appearing in medical journals, generally recommend proprietary products, would jump to the conclusion that, if such an article was written, it probably had a venal origin, or else it was probably written by a man of little repute. The chewing gum concern would have made a stronger appeal had they quoted from the article verbatim, and then added their own comment to the effect that if the profession wanted a chewing gum here was one the manufacturers could recommend."

The editor of the *Journal of the American Medical Association* will find it impossible to make his would-be advertisers believe the plain truth of his words.

F. ST. J. S.—The condition can hardly be prescribed for on so brief a description; can more particulars be given?

ON

## THE PROBLEM OF HYGIENE IN EGYPT.

*Being Three Lectures delivered at the Summer Session, 1919,*

BY ANDREW BALFOUR, C.B., C.M.G., M.D.,

DIRECTOR-IN-CHIEF, WELLCOME BUREAU OF SCIENTIFIC RESEARCH;  
LATE PRESIDENT, EGYPTIAN PUBLIC HEALTH COMMISSION.LECTURE III.—THE SOLUTION OF THE PROBLEM:  
PRESENT AND FUTURE.

In our first lecture we considered the more obvious causes which produce the problem of hygiene in Egypt; in our second we discussed those which are more obscure and which, being intimately bound up with the form of central administration that is in vogue, led to a review of the latter. We will now turn our attention to the provincial organisation and see not only what problems it furnishes but how it meets the needs of health in the towns, in the villages, and in the rural parts of the Mudiriya, as the provinces are termed in the Arabic of Egypt.

## PROVINCIAL ORGANISATION IN THE PRESENT.

It is usually a relief to leave a city like Cairo or Alexandria and fare forth into the green of the Delta. The air is fresh, the sky is, as a rule, blue and cloudless, and though the scenery is monotonous the rural life is interesting and there are many spots which are eminently picturesque. In Upper Egypt one is not often far from the Nile and the Father of Waters rarely fails to please the eye and quicken the imagination.

If there is not very much to entrance the botanist and the zoologist, at least compared with some other Eastern lands, there is always something in Egypt to catch the sanitary eye and too often something also to titillate the sanitarian nose. The sanitarian views a reedy water channel, and while he thinks of it turning the black alluvial soil into the richest of muds and benefiting the patient cultivator, he knows that as a source of drinking water it is, to say the least, doubtful; for may it not in parts be full of cercariae or constitute a medium wherein typhoid or dysentery bacilli lurk, or, given the opportunity, may it not harbour the cholera vibrio? He notes the rich mud and the fellaheen ankle-deep at work in it and wonders whether or not the larvae of ankylostomes are busy finding their way through the skin of the peasant farmers. A grove of stately date palms confronts him, and while he admires them for their beauty and their fruitfulness he cannot forget the filthy manner in which agwa is prepared. His eye roves over the picturesque, nondescript village huddling on its little mound hard by the birka with its green scum and countless frogs, and though he admits it has a beauty of its own, he cannot but recall its flies and their breeding places, its rats and their fleas, its inhabitants and their lice, and instinctively he thinks of dysentery, of plague, of typhus, and relapsing fever. And so on and so forth. You will doubtless say what a very unpleasant mind your sanitarian must have! It is one thing to find sermons in stones and books in the running brooks, but surely to conjure up parasites and disease in well-nigh every feature of the landscape is a dismal form of mental recreation, a morbid type of fancy. I grant you such is in some measure the case, but the pity is that there is good cause for these imaginings. And yet the sanitarian is, as a rule, no pessimist. He knows these evils exist, but he also knows that they are one and all preventable, and his ambition is to remedy them so far as it lies within his power to do so. Their presence arouses, or should arouse, the fighting spirit in him, and, believe me, there is something stimulating and satisfying, as well as disheartening, in waging war against the forces of disease and death in such a country as Egypt.

*Divisional Inspectors.*

That is one reason why we are always likely to find able young men eager to take up the work of divisional inspectors

who, as you will see from the graph (Graph 1, Lecture II.), head the list of those who fight the battle of health in the Egyptian provinces.

One reason why the contest has not been so victorious as might have been hoped is to be found in the paucity of the numbers of these divisional inspectors. There are 14 provinces in Egypt, many of them large, most of them exceedingly populous. The number of inspectors has in the past been woefully few, and during the war it diminished almost to vanishing point. Furthermore, the inspectors were not resident in their districts. As a rule, they were constantly on the move, and so were not in the best position for getting into close touch with the populace and the prevailing conditions. Their duties also were far from being merely sanitary, as they had to exercise a supervision over the provincial hospitals, the medico-legal work of the Markaz doctors, and all the hundred and one matters which are intimately bound up with health problems in the provinces.

*Provincial Hospitals.*

A glance at Graph 1 shows that the provincial work is divided into that concerned with hospitals and that which is directly under the charge of the Markaz and outpost doctors and which is a regular *olla-podrida* of widely differing duties. The question of provincial hospitals need not detain us. In discussing Section II. of the Central Administration we saw the problems they present. It is time to turn to the Mudiriya health inspectors, who are, for the most part, stout, worthy, and elderly Egyptians who form the link between the English divisional inspectors and the Markaz doctors, and are virtually the medical officers of health of the provinces. Being as a rule advanced in years, they are not generally energetic, they are not sufficiently well paid, and few of them do much in the way of private practice. Their chances of promotion are very small, and they tend to become inactive and to concern themselves chiefly with office work. Here and there you will find a keen and able man, but, for the most part, the Mudiriya health inspectors may be described as genial anachronisms.

*The Markaz Doctor.*

And now we come to one of the most important props of the health fabric in Egypt—the Markaz doctor—a Markaz being a section or district of a province. It may be a populous and prosperous district, so much so that one solitary medical officer may have as many as 100,000 people nominally under his charge. In such a case the majority die what the old Highlander called “natural deaths,” for the doctor cannot get anywhere near them when they are ill. All the same he probably enjoys a most lucrative private practice to which his government duties may or may not play second fiddle. On the other hand, the Markaz may be poor and sparsely peopled, no great catch for the young and pushing graduate from the Kasr-el-Aini School of Medicine who finds himself in such a district with very poor official pay, say £E.12 a month, and but little opportunity of supplementing it in any way.

Whether his Markaz is good or bad, however, he is expected to perform the manifold duties set forth on the list shown in Graph 1. One has only to read the long column to realise that in the great majority of cases the Markaz doctor is set an impossible task, at least while his numbers remain as limited as they are at present. He is supposed to deal with infectious diseases both from the clinical and the preventive aspects, much of his time is occupied with medico-legal work, of which there is a superabundance in Egypt, and which often proves remunerative in several directions, and he is expected to control general sanitation. Consider what this means in a large district studded with villages and seamed by canals and irrigation channels. On an ambling ass the Markaz doctor, surmounted by his red tarboosh, jogs hither and thither, often covering many miles a day. He may have to see that a birka is filled up, he may have to inspect a school. The water-supply of a mosque requires his attention, he has to furnish a report on the sanitary condition of a Government building. Questions of the regulation of water intakes fall to his share, as do those of street cleaning, slaughtering places, the enclosure of waste lands, and the selection of sites on which town refuse and fosse contents can be dumped.

*His Multifarious Duties.*

As if all this were not enough, he has still to keep an eye on offensive trades in his district, see to the registration of births and deaths, superintend the vaccination of the community, attend to the dispensary, examine prostitutes in places where there are no hospitals, carry out various duties connected with cemeteries, in one or other of which he must surely sometimes wish he were quietly at rest. Moreover, he attends the meetings of the local commission as public health delegate, he investigates contraventions against the law regarding the practice of medicine, he looks after pilgrims, and keeps an eye on such incomers to his district as are under the passenger control regulations. He is responsible for the sanitary state of fairs, he examines and reports on sick Government employees, he also examines the village police, and finally inspects the bodies of those who die uncertified. In addition, he usually earns his living by private practice, and presumably he eats, drinks, and sleeps!

But you will say, "The poor man must have a large staff under him to aid him in these multifarious duties." Not at all. Look at the graph. It is true that the Omdahs and Sarrafs, head-men of the villages, register the births and deaths, but I fear they often give the conscientious Markas doctor more trouble than assistance. It is true the barber, if he happens to be efficient, may render considerable aid; but, after all, who is the barber? He is merely an unqualified person who in all probability has inherited his office, and though he may be highly intelligent and carry out his own minor duties of vaccination, cupping, and so forth, in a satisfactory manner, he cannot, in the nature of things, take much of the load off the shoulders of the Markaz doctor. There is no one else, for the Daya, as we have seen, if not negligible, is usually dangerous. It is only when epidemics occur that our harassed friend gets special help and even that is only in one particular. In the strict sense of the term there is no sanitary staff whatever and rural Egypt lies largely at the mercy of the microbe, the helminth, and the fly.

*Administration in the Governorates.*

You will note that under the heading Provincial Organisation mention is made of the health administration in the Governorates—that is to say, in Cairo, Port Said, Suez, and Damietta. Cairo and Port Said have medical officers of health; Suez and Damietta so-called health inspectors.

We considered the conditions in Cairo in our first lecture and need not recapitulate. Of late years things have altered greatly for the better in certain localities, thanks to hard work on the part of a very capable medical officer of health and to the partial completion of the great drainage scheme, the sewers of which cast their contents upon the desert far from the city and cause it to blossom, if not like the rose, at least like a nosegay, for the trees and verdure of the sewage farm now form a feature of the landscape, and there was never yet a sewage farm without an aroma.

Recently, also, the Public Works Department has been erecting public conveniences in the streets, and these, well-designed and with the latest sanitary improvements, must be regarded as a very considerable hygienic advance. There still remains, however, a great necessity for public drinking-fountains supplying pure water. The latter is available, for there is a large installation of mechanical filters, but it is not to any extent at the service of the poorer parts of the populace.

*Cairo, Port Said, and Alexandria.*

The Qism medical officers whom you see mentioned on Graph 1 are really analogous to the Markaz doctors of the provinces so far as their work is concerned. Each looks after a division or district of the city, and though he has not to traverse great distances like his country confrère, he has more or less the same cheerful variety of duties and has very little leisure to devote himself to what we may call pure sanitation. At the same time he has assistance which the Markaz doctor lacks, for there are properly organised disinfecting gangs and the rudiments of a sanitary staff. Cairo, indeed, has really made a start in the right direction, though it is still a very long way from a hygienic millennium.

Port Said is also somewhat progressive, for under the British medical officer of health there is a senior medical man who devotes himself almost entirely to sanitary work, while his junior is entrusted with purely medical duties.

Very different is the state of matters in Alexandria, which, as we have stated, is a municipality and hitherto has been almost entirely a law unto itself. In other words, it has not been controlled by the Public Health Department. The latter has merely had the power to intervene when some epidemic raging in the city threatens danger to other places, a fine example of shutting the stable-door when the steed has been stolen. The Qism doctors who are supposed to safeguard the public health in Alexandria are not trained sanitarians and are permitted to engage in private practice. Though there is a medical officer of health, there is no expert control. There are no qualified sanitary inspectors. Indeed, the whole health administration of this wealthy port is radically wrong, and it is no wonder that the insanitary conditions we described in our first lecture have been the subject of adverse comment in the press, and that repeated outbreaks of typhus fever have evoked well-merited criticism and a clamour for reform.

*FUTURE SANITARY ORGANISATION.*

Our review of existing health problems in Egypt is now at an end, and we turn to the future. Shortly after the retirement of the last Director-General of the Public Health Department, the High Commissioner appointed a Commission to inquire into the future organisation and work of that department. Very nearly a year ago the Commission began its sittings, examined many witnesses, studied much documentary evidence, carried out numerous inspections, and in the fullness of time was delivered of a report, with the salient features of which we shall now deal. Whether or not the problem of hygiene in Egypt will be solved if the recommendations of the Commission are adopted and carried into effect no one can say. Egypt being Egypt, it is quite possible, nay probable indeed, that the proviso will never be forthcoming, at least in toto. Still, it may be said that the council of four<sup>1</sup> constituting the Commission found themselves in complete unanimity and that what public opinion exists in Egypt, generally speaking, approves their findings.

*A MINISTRY OF HEALTH.*

What are the findings? I direct your attention to a new graph (No. 2) and you will note at once the words "Ministry of Health." Despite some evidence to the contrary, the Commissioners were persuaded that the establishment of such a Ministry was essential. The reasons for this belief have already been recorded in the weighty words of Dr. Cyril Goodman, who further states:—

"The reorganisation of Egypt on constitutional lines, rendered necessary by the Protectorate, offers a peculiarly favourable opportunity of giving public health a place in the constitution commensurate with its importance to the country. Public order, finance, irrigation, agriculture, education and public health constitute the six principal interests of Egypt and the six principal duties of Great Britain towards its Protectorate. The present scheme of government includes in its governing body representatives of each of these interests, with the exception of public health. If the policy of Great Britain towards Egypt is to be placed on the broadest basis of material, mental, and physical advancement of the people then public health must be given without delay representation on the Council of Ministers, on the Council of Advisers, and it must be recognised as the direct adviser of the High Commissioner on matters of public health.

It must be frankly stated that those who, while expressing sympathy with the idea, urge delay in its execution must be considered as inimical to the movement itself, for a successful public health policy must grow with the fundamental institutions of the country. It must be built into, not be grafted on, the constitution. If, therefore, the importance of public health in Egypt is sufficiently great to justify its inclusion as a Ministry amongst those which direct the policy of the country, then it is clear that during and not after the remodelling of the institutions of the country is the proper time for that inclusion."

<sup>1</sup> The Commission was composed as follows:—President: Lieutenant-Colonel Andrew Balfour, C.B., C.M.G., R.A.M.C. Members: Lieutenant-Colonel G. E. F. Stammers, R.A.M.C.; Mr. E. S. Crispin, Director, Medical Department, Sudan Government; and Dr. Charles Todd, O.B.E., Director of Laboratories, Department of Public Health Secretary: Mr. H. Sheridan.

MINISTRY OF HEALTH.

MINISTER OF HEALTH.

Provincial and Quarantine Laboratories.

PROVINCIAL ORGANIZATION.

*The Head of the Ministry.*

It remains to be seen how such a Ministry should be constituted. At its head there must, of course, be a Minister—an Egyptian—and he must be an official thoroughly versed in public affairs, interested in the welfare of the people, in social problems, and in scientific progress. It is not impossible to find such a man in Egypt, and, once found, his words would carry great weight in the Council Chamber. He need not of necessity be a medical man. Indeed, the appointment of a layman would possess certain advantages, as it would ensure that the Minister of Health was on the same footing as other Ministers, was appointed for the same political reasons, and would be interchangeable with them if a Ministerial rearrangement was required. In immediate command it is essential to have a British Under-Secretary of State, a medical man, who must needs possess a long and intimate knowledge of health matters in Egypt and be conversant with the intricacies of governmental machinery in that country. He will control the sanitary, epidemic, and medical work of the Ministry. As a glance at the graph shows, there will be a Department of Medical Education under him, a new departure and one necessitated by the present state of Egyptian affairs. His duty will be to frame future policy and indicate how health legislation should best be carried out, to see that the work is conducted upon a sound scientific basis and that scientific research, which alone can point the way to reform, receives due encouragement. He must also be capable of taking that broad view on which so much depends and possess those qualities of tact and firmness which count for so much in Eastern lands. Finally, as the Commission reported, "it is essential that he should have direct access to the High Commissioner, so that, armed with the weapons of an expert, he may be able to plead his cause to good effect."

The main driving force of the Ministry will, however, undoubtedly be the Director-General, who should not be too old a man. Public health work is a campaign against Field-Marshal Death and his redoubtable generals—to wit, Dirt, Destitution, Disease, Ignorance, Superstition, and, by no means the least doughty, the fighter with the double-barrelled name, General Vested-Interests! Hence, as in war, the commander must unite a certain degree of youthful energy and vigour with the experience and powers of judgment which are so necessary. Not only must he be a capable organiser, but he must combine strength and sympathy in his work, for, lacking sympathy, he will probably fail in a land like Egypt.

*The Technical Adviser.*

The next post is a new one, though it exists unofficially. It is that of Technical Adviser and Director of Medical Intelligence. I am not sure but that it is the most important of all, and though the duties of the post would be chiefly advisory, its holder would not be wholly divorced from administrative work, for, as you will observe, he would control the scientific side of the Health Ministry in so far as hygiene is concerned. Here is what the Commission say about this appointment:—

"We consider a post of this nature to be of the very greatest importance. The Technical Adviser would not only act in that capacity to both the Under Secretary and the Director-General, but he would conduct a Bureau of Information. Controlling the main library, keeping himself closely in touch with what goes on in other countries, studying the vast literature, corresponding with similar departments of other Governments, he would be in a position to furnish invaluable information to the chiefs of the various Sections, and, by issuing instructive pamphlets and circulars both to Public Health officials and to the medical profession in Egypt, he might speedily make the Ministry of Health a real power in the land. Moreover, he would collect and collate information from local sources, so that at any time he would be in a position to advise on problems arising in Egypt itself. The lack of a bureau of this kind in the Medical Department of the British War Office has made itself severely felt in the various tropical and subtropical areas of hostilities. Such work, properly carried out, effects great saving in both time and money, and possibly does more than anything else towards making a Government Department really efficient and up-to-date."

*A Museum of Medicine and Hygiene.*

A further proposal of the Commission is the establishment of an Egyptian Museum of Medicine and Hygiene, which

would be of an educational nature, and, under the guidance of the Technical Adviser to the Health Ministry, should prove itself a stimulus towards sanitary reform. It is not suggested that this should be a Government undertaking. So truly national a project may well find support amongst the wealthy and influential of Egypt. As the Commissioners remark:—

"There is undoubtedly a need for some such institution in Egypt, where, in a graphic manner, information will be furnished, both to officials and to the populace generally, as regards the diseases of Egypt, the insanitary conditions prevailing in the country, methods of dealing with epidemics, and means of rendering towns and villages clean and healthy. The work of hospitals and dispensaries would be illustrated, the rôle of insects in disease explained, the danger from faulty and deficient dietaries set forth, together with measures of prevention and cure. In fact, a great centre of instruction would be established—a school where one might learn with little effort, where interest would be excited and sympathy aroused."

*SECTIONS OF THE CENTRAL ADMINISTRATION.*

At this point I may mention that the Commission recommended a Board of Health for Egypt, a body which undoubtedly would be of benefit in many directions. The results of its deliberations, as suggested by Dr. Goodman, should be published for the information of the public. We need not here enter into the question of its constitution, but will continue our consideration of the Central Administration under the new scheme. Three of the sections we previously discussed become departments and one disappears, the ophthalmic section being, for purposes of economy and facility in administration, attached to the Department of Medical Services, which is the old hospital section.

The new Department of Sanitary Services will require a director intimately acquainted with Egyptian conditions. His duties have been set out in rather more detail than were those of the director of Section I., and the only one of them to which reference need now be made is that indicated by the term sanitary training centres. As will in due course be seen, these are intended as schools of sanitation for training certain inspectors of nuisances whom it is proposed to create for the purpose of dealing with village sanitation. The latter, which, as you will see, heads the list, is perhaps best considered under the proposals for provincial administration.

The Department of Epidemic Services shows little change from Section IV., save that the suggestion is made to bring sea quarantine under it. This is a difficult matter, for it involves complex international questions, and no one can say how it will yet be settled. Inland water transport is mentioned, as it plays, or may play, an important part in the spread of plague and cholera when these diseases are epidemic in Egypt.

The Hospital Section becomes the Department of Medical Services, and the shortcomings which have been mentioned indicate the measures required for their remedy. In addition to an increase in general and infectious hospitals and a new policy as regards the treatment of prostitutes in the former, it is essential that technical inspectors be appointed to visit periodically the 23 general Government hospitals and to reside in them from time to time for limited periods. In some of these hospitals, also, post-graduate courses might with advantage be instituted.

*Absorption of Other Medical Services.*

The medical service of the Ministry of Education might with advantage be brought under the control of the Ministry of Health. The medical inspection of school children in Egypt is of the highest importance and requires to be developed with the help of technical inspectors. It will be seen that those medical services which have been outside the fold or have strayed from it are to be shepherded into it, so that the whole health work of the country may be properly coördinated, while the medico-legal work no longer figures under general sanitation, but is brought into this department. It would, indeed, be well if some of the burden of this class of work could be borne by the Ministry of Justice, but the question is a difficult one, and the Commission had to content itself with expressing some pious hopes in that direction. Certainly a great deal of the time of the Markaz doctors is taken up with duties which are nearly as much legal as medical.

The medical control of prostitution and venereal diseases has been relegated to this department, and only those who have carefully studied the problem in other countries can appreciate all that it involves. More lock hospitals are required, clinics for the treatment of venereal diseases must be established, the populace must be instructed, and facilities for preventive treatment provided. The whole question bristles with difficulties, but we know that these exist to be overcome, and money and determination, and above all things common-sense, can work wonders.

#### *Provision for Incurables and Lepers.*

As regards provision for incurables and lepers, I cannot do better than quote again from the Commission's report:—

"Homes for incurables would meet a great need in Egypt. The country is full of crippled and debilitated mendicants, for whom little or nothing is done. The *tekiyas* of the Ministry of Waqfs deal with a few incurable cases, but the number of these establishments is quite inadequate. These unfortunate individuals are often beggars, are liable to become foci of infection, and present a problem which can only be solved by making provision for them. Even then, only a certain proportion of them can be housed, but this will help in some measure. So far as Cairo and its neighbourhood is concerned, the proposed transference of Qasr el 'Aini hospital from its present site would leave vacant a suitable building for a hospital for incurables; others, however, are required in various parts of Egypt. This is not the work for the Ministry of Health, except as a controlling and inspecting body.

"It would appear to be the privilege of the Waqfs Medical Services to make such provision. Amongst charities, that which benefits the aged, the infirm, and those who are beyond the skill of the physician and surgeon surely holds a high place. It is true that some waqfs are allotted by their donors for definite purposes, but we are assured that there are ample funds on which there is no reservation and which might well be devoted to this good cause.

"Closely associated with the question of incurables is that of lepers. We have been unable to obtain any reliable statistics as regards the present prevalence of leprosy in Egypt, but there are undoubtedly a number of lepers in certain places—for example, Damietta. There is nothing to prevent them from handling foodstuffs intended for sale; and though leprosy does not appear to spread much in Egypt, and though the channels of communication from the sick to the sound are not fully known, such risks should certainly not be permitted. Even if, from the public health point of view, it may not seem very necessary to segregate lepers in Egypt, there is the humanitarian aspect of the case to be considered, and an asylum is undoubtedly required for maimed and helpless lepers, as well as for those who are probably an active source of infection. A leper colony in which work could to some extent be carried out on the land would be a wise provision, and the attention of the Ministry of Waqfs might well be drawn to this charitable object.

It will be seen that the lunatic asylums should form a section of the Health Ministry under a Director of Lunacy. This is in accord with the modern trend of thought as regards the work of the alienist. Lunatic asylums are, however, so specialised that they cannot be grouped with other hospitals, but must form a separate department.

#### *MEDICAL EDUCATION IN EGYPT.*

And now we reach a very important subject—that of medical education in Egypt, which, however, can only be very briefly considered. We saw that the Kasr-el-Aini School of Medicine owed its foundation to Clot Bey. It has proved, especially of late years, a most useful institution both in the way of teaching and of research, and its professoriate has included men of European reputation. Unfortunately, the school is now too small to meet the needs of the country, and though it attracts the intellectual élite from the secondary schools the Ministry of Education has to refuse many applications owing to lack of accommodation. The vast majority of the students who pass through the school find employment in the Public Health Service, and in the absence of any University system in Egypt it is deemed advisable to bring medical education into the Ministry of Health, there to be placed under the control of a director, who must of necessity be given a free hand not only as regards medical education, but with respect to the training of dentists, pharmacists, nurses, midwives, and dayas. Medical research work, demanding access to clinical material and requiring the calm of academic surroundings for proper development, would be conducted in

the laboratories of the school of medicine and would be distinct from the applied research work of the public health laboratories, which is of a different type though equally important.

The curriculum of the school can be improved in certain directions, as by establishing instruction in diseases of children and in protozoology. A chair of hygiene should undoubtedly be instituted and a diploma granted, either in public health alone or in tropical medicine and hygiene. Like the medical school, the great teaching hospital of Kasr-el-Aini requires extension and improvement. Indeed, a new building on a new site has long figured on a programme which has never been fulfilled. Facilities for dispensary work might prove valuable, and the question of training Egyptian women doctors is one meriting serious consideration.

In Egypt there is also great need for a powerful board to control the practice of medicine, dentistry, and pharmacy, and to deal with all questions of malpraxis and vivisection.

It will be seen from the graph (No. 2) that it is proposed in certain respects to expand the work of those public health laboratories. Protozoology requires more attention than hitherto, and food control and sewage control services must be established. As will be noticed, there is a plan to decentralise the work in some measure by means of provincial laboratories, while the existing quarantine laboratories should be brought under the sway of the Director of Medical Intelligence. The chief sanitary engineer of the old graph becomes a Director of Sanitary Engineering, a subject which will undoubtedly become increasingly important as schemes for drainage, water-supply, disinfection, and so forth develop.

#### *THE SOLUTION OF PROVINCIAL ADMINISTRATION.*

Such are the main recommendations of the Commission as regards central organisation. Let us see how it proposes to solve the problem in the provinces. Recognising that there are far too few divisional inspectors, it recommends an ample increase in their numbers and insists that they should live in their districts, be housed, well paid, and given every facility for getting about rapidly. Opportunities should also be afforded them for seeing in rotation something of the Central Administration and gaining an insight into the work of those departments of the Ministry, the chief posts in which some of them will one day fill.

#### *Introduction of the Sanitary Inspector.*

There is nothing very novel in these recommendations, but an entirely new idea, so far as Egypt goes, is voiced by the suggestion to introduce qualified British sanitary inspectors, one of whom would be attached to each divisional inspector to aid him in his work and, under certain conditions, to train those inspectors of nuisances whom we have mentioned and who figure in the graph. There can be no doubt that intermediaries of this kind are greatly needed. If the right class of man is obtained—and he should be forthcoming in greater numbers now the war is at an end—he should go a long way towards solving some of the problems I have mentioned, for efficient inspection means everything in this kind of sanitary work. Qualified sanitary inspectors of this type have proved their value in the Sudan. They are employed under the Colonial Office administration in various parts of Africa, and I hope to see the day when it will be possible to train them in the rudiments of tropical hygiene before they leave this country for their posts abroad. Their ordinary training is excellent so far as it goes, but at present time is wasted after they reach the tropics in giving them instruction in antimosquito measures, in native habits and customs, in conservancy methods in vogue in hot countries, in new aspects of the fly question, in those improvisations which form so great a part of the sanitarian's outfit abroad, and in all those *minutiae* which mean so much and which can perfectly well be imparted to them by one having experience. It is true that many have become *au fait* with these matters during the war, but we have to think of the future, and the sooner this training is instituted the better for the Empire. It has been too long delayed.

We need not again consider the strictly medical work in the provinces, but from what has been already said it is clear that the Mudiriya health inspectors should be better paid and have better prospects. The posts should be filled by

younger and more energetic men who may be expected to take an active interest in their duties, especially if they are diplomates in public health.

#### *Two Categories of Markaz Doctor.*

And now we come again to our friend the Markaz doctor. What is to be done about him and his manifold perplexities? Two courses may be followed. The ideal scheme, and one which eventually must be adopted, is to divide the Markaz doctors into two categories according to the work, sanitary and medical, as shown in the subjoined table:—

Markaz Doctor in charge of Public Health Work (excluded from private practice).	Markaz Doctor in charge of medical work (allowed private practice).
General sanitation.	Communicable diseases (clinical).
<i>Établissements insalubres.</i>	Medico-legal examinations and reports.
Communicable diseases (public health aspect).	Dispensary.
Vaccination and vaccination inspections.	Prostitutes.
Pilgrims.	Medical Commission work:—
Quarantine.	Examination of sick Government employees.
Passenger control.	Examination of <i>ghafirs</i> .
<i>Mûlêds.</i>	Prisons (in certain places).
Schools and <i>kuttabs</i> (sanitation).	Schools (medical).
Prison lock-ups (sanitation).	
Cemeteries.	
Registration of births and deaths.	
Public health delegate on Local Commission.	
Public health representative on the Markaz Sanitary Commission.	
Contraventions against public health laws and regulations.	

The Markaz doctor engaged on sanitation would not be allowed private practice, would be freed from medico-legal work, and would have an initial salary of £E.25-30 a month. He would also be pensionable. From this category the Mudiriya health inspectors would be chosen.

The Markaz doctor engaged on medical work would be paid as at present, would carry out the official duties listed in the above table, and would be on contract until found satisfactory. He could then be placed on the cadre. As at present, his chief prospects would be in the direction of private practice.

#### *Provisional Measures.*

Unfortunately, at present this scheme cannot be carried into effect, for there are not enough Markaz doctors in Egypt, there are not enough private practitioners, there are not sufficient medical graduates. Still, it might be tried on a small scale in certain districts, a course the Commission recommended.

The second plan is to multiply the number of doctors in each Markaz, strictly defining their respective areas, and making no change in the nature of their work or in their pay. Even this simple solution of the problem will be difficult of realisation until the medical school is enlarged and is able to cope with the medical needs of the country. How true is the old proverb, "Things move slowly in the Nile Valley!" "Haste," however, we know, "is begotten of the devil," and if we can only combine the slowness with sureness no great harm will be done, provided that slowness does not degenerate into sluggishness, a very different affair.

#### *The Inspector of Nuisances and Sanitary Barber.*

Inspectors of nuisances may be recruited from the ranks of the better educated sanitary barbers or from men of the artisan or mechanic class, or possibly even from ex-non-commissioned officers of the Egyptian Army. Trained by the sanitary inspectors, paid out of local funds, in close touch with the people, the inspector of nuisances would supervise the scavenging and cleansing of villages, and, if village latrines and incinerators prove feasible, he would see that they are properly used and kept in repair. He would inspect water-supplies, markets, *birkas*, and other mosquito-breeding places. He would endeavour to show the people how their villages could be improved and how they could live in more cleanly and also more comfortable surroundings. He should have some knowledge of building construction, and of the rôle of flies in the spread of disease.

The sanitary barber, who should also be paid, would, in addition to his present duties, furnish information on matters of public health interest occurring in the village, while a conservancy staff would represent the lowest rung in the sanitary ladder.

#### *The Working-out of the Scheme.*

Here, then, is a definite system, providing, apparently, for all contingencies, costly no doubt but not unduly so, and

avoiding too heavy a strain upon the central treasury. It remains to be seen if it will be adopted in its entirety and, if adopted, how it will serve the medical needs of Egypt. It has been said that the report of the Commission afforded cause for complaint by the Egyptian Nationalists inasmuch that, save in the case of the Minister, all the higher posts in the Health Ministry were allotted to Britishers. The statement is doubtless true, but requires to be qualified, for, owing to the lack of technical training which has been mentioned, there are at present no Egyptian doctors capable of holding these posts. Furthermore, I would like to point out that the Commission expressly recommended an improvement in the status and pay of the Egyptian Mudiriya health inspectors and advocated their advance to divisional inspectorships as soon as possible. Their report also provides for a large increase of Markaz doctors and the creation of a new class of Egyptian employees—namely, the inspectors of nuisances. The national aspect of the question was duly and sympathetically considered and, as has been stated, recommendations were made which, if carried into effect, will create a body of Egyptian hygienists capable of serving their country to the best advantage in the interests of the public health.

#### *Application to Urban Areas.*

In the case of the individual towns measures closely resembling those just detailed must be applied. Cairo requires qualified sanitary inspectors and inspectors of nuisances. So does Alexandria. The latter city must no longer be permitted to act as a law unto itself in public health matters. The Commission recommend that a Controller be appointed by the Ministry of Health, which itself should approve all public health appointments. The Qism doctors should not be allowed private practice and should devote their whole time to public health duties, in which they should be specially trained. In short, a radical change is needed if the stigma now resting on the city is to be removed and the health of its populace safeguarded. At the same time, it is only fair to state that the chief engineer of the municipality has been busy with schemes for replacing the *echêches* of which I spoke in the first lecture, by model dwellings. Building regulations have also been framed and a town plan introduced, so that the outlook is distinctly more hopeful. As regards other towns, the method in vogue at Port Said may be followed with advantage until such time as each is able to work out its own sanitary salvation on a sound basis of local self-government.

Time does not permit a discussion of other points considered by the Commission, such as the future of the medical services of the Ministry of Waqfs, that department which controls large funds earmarked for charitable purposes, the amendment and progress of public health legislation, the dissemination of information, and the great desirability of lay officials taking a real interest in sanitary reform and keeping themselves acquainted with what is happening in the hygienic world of Egypt.

#### THE REMOVAL OF A REPROACH.

It all sounds very simple, but in reality how hard it is to make headway against ignorance, inertia, and prejudice! Let us, however, hope for the best.

Along with this reform, or rather advance, in public health administration an active campaign should be instituted against these three deadly enemies of the fellaheen—bilharziasis, ankylostomiasis, and pellagra. Leiper and his colleagues have already thrown much light on the first-named, we know a great deal about the second, the third alone remains a mystery. Given money and research on sound lines, the mystery will assuredly vanish, and given funds and a progressive sanitary policy the people of Egypt will be freed from the burden of all three diseases.

I have spoken in vain if it is not apparent that the sanitary condition of Egypt still remains in many respects a byword and a reproach. Great Britain has declared that ancient land a Protectorate, and has protected it from the Teuton and the Turk on the east and the Senussi and the Turk on the west. There are, however, other foes of its own household, and unless this country realises its responsibilities and undertakes to rout the forces of disease which hold Egypt in thrall, it will have failed in its duty, and one day there will be written of it, as there was of Belshazzar of Babylon, "Mene, mene, tekel, upharsin"—Thou art weighed in the balances and art found wanting.

## A STUDY OF HYPER-ADRENALISM:

ITS INFLUENCE IN PRODUCING CONGENITAL PYLORIC HYPERTROPHY AND SUBSEQUENT OBSTRUCTION.

BY GEO. R. PIRIE, M.B. TOR., M.R.C.P. LOND.,

MEDICAL REGISTRAR AND PATHOLOGIST, RESIDENT MEDICAL SUPERINTENDENT, AND CASUALTY MEDICAL OFFICER FOR THE PERIOD OF THE WAR TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

FROM the time, over 20 years ago, when John Thomson and Finkelstein began to associate specific signs and symptoms in babies with a large thickened pylorus (until then recognised only in the post-mortem room), there have been several theories advanced and much discussion has taken place as to the pathogenesis of this condition.

In the typical case there is undoubted true hypertrophy. There is an increase in both the number and size of the circular muscle fibres, as has been repeatedly demonstrated. It is concerning the cause of this hypertrophy that there has been so much speculation. The explanation most commonly offered has been that the hyperplasia of the musculature of the pylorus is caused by an error in its development. Apart from the fact that it is very difficult to conceive of any error in development resulting directly in true hypertrophy, there is neither corroborative evidence nor any analogous condition to substantiate this theory. The natural explanation of hypertrophy is overaction or spasm. Still and Thompson were inclined to attribute it to spasm induced by a lack of coördinate action between stomach and pylorus.

*Hyper-adrenalism before Birth as the Chief Cause of the Spasm.*

It is the purpose of this paper to suggest that the spasm inducing hypertrophy is primarily due to hyper-adrenalism before birth, and that other subsidiary post-natal causes determine the persistence or recurrence of the spasm. This condition is due to a lack of balance between the secretions of the various endocrine organs in the process of their development and involution, which may result either in a relative or an absolute hyper-adrenalism.

Whether this condition is congenital or not is also a much discussed point. The balance of evidence seems to indicate that it must be congenital. It is true that the majority of cases first show symptoms at about the third week. It is equally true that, in many instances, the child forcibly ejects the first and every subsequent feed. Moreover, at operation, the hypertrophy is usually found to be so marked that it is difficult to believe that it could have arisen during extra-uterine life. Further, many babies are presented for examination and treatment exhibiting gastric peristalsis and projectile vomiting. In the absence of a palpable tumour, congenital pyloric stenosis should not be the diagnosis. A careful history and observation will show that varying amounts of food pass through the pylorus, inasmuch as there are occasional periods without vomiting and with normal stools. The symptoms are due to improper feeding, gastritis, or phimosi among many other causes. The child is treated empirically, by regulation of its feeding, proper management of the gastritis, or the performance of circumcision. Thus the symptoms are relieved without any apparent permanent change having taken place in the muscle of the pylorus. If the spasm persisted for a long time, as it does in many instances, hypertrophy sufficient to warrant surgical intervention might result. This never happens in practice. Therefore it must take a great deal longer for spasm to produce hypertrophy than many have hitherto thought.

From these considerations, then, one is forced to the conclusion that the hypertrophy in the cases under consideration exists from before birth, and that whatever influence has been at work to produce this change must have existed for a long time. This being so, one must look for some ante-natal force which is capable through its prolonged action of producing this change. It is not, then, the occurrence of hypertrophy some time after birth which determines the onset of symptoms. This may exist in widely varying degrees, and it is the degree of added spasm from one of many causes which will determine the time of appearance and severity of the symptoms in those cases where the amount of hypertrophy at birth is not excessive.

Swale Vincent, Sharpey Schafer, Priestly, Elliott, and many others have shown how important from a developmental point of view are the endocrine organs and how finely adjusted is the balance between their hormones.

Medical literature is full of reports as to the breaking down of this balance in adult life. If this is so, how much more readily may one accept the possibility of a lack of balance at birth and before, when developmental requirements are urgent and physiological processes so active. If this disturbance in balance results in a relative or absolute excess of the suprarenal medullary hormone, spasm of any non-striated muscle may result. Keith has shown that both the pylorus and the medulla of the suprarenal gland become differentiated at about the third month of intrauterine life. Since excessive suprarenal secretion produces spasm in non-striated muscles, this would allow plenty of time for spasm induced by any excessive suprarenal secretion to bring about hypertrophy. He also states that before birth the gland is larger than the kidney, and at birth may be the same size. After that it rapidly reaches its normal relative size.

Sharpey Schafer, in his blood pressure experiments with adrenalin, noted that spasm of the pylorus was produced when he injected the secretion into the suprarenal vein. It is not claimed for a moment that adrenalin has a selective action on the muscle of the pylorus. The same experiments showed that spasm was produced at many places in the gastro-intestinal tract—e.g., the ileo-caecal valve and the junction of the pelvic with the rectal colon. The fact that untoward results of this spasm are noted so rarely in situations other than the pylorus is explained by the peculiar anatomical and secretory relations existing between the stomach, pylorus, and duodenum. This relationship favours the establishment of secondary vicious circles which would determine the persistence or recurrence of spasm. The objection might be raised that if hyper-adrenalism can exist in the ante-natal condition we should see more frequent evidence of its effects after birth. The reason that we do not is that the degree of hyper-adrenalism can never be constant, and only those cases would show symptoms where it is marked. In the post-mortem room one has noted many times slight thickening of the pyloric muscle in the bodies of babies who have died without any clinical evidence of obstruction at the outlet of the stomach. This thickening is quite apart from the apparent hypertrophy which sometimes occurs just at death, and is noted in bodies from which rigor mortis has passed off. Whether this thickening is congenital or not is, of course, pure conjecture. It may have been due to prolonged spasm from one of the several causes mentioned elsewhere. Both in these cases, and in those dying with true hypertrophic stenosis, has vain search been made for any abnormal or unusual appearance of the suprarenal gland. If the assumption of ante-natal hyper-adrenalism is correct, there need be no abnormality of the gland apparent after birth. As most of the examinations are made when the infant is at least several weeks old, the process of involution would be complete and only the effects of the plus secretion before birth would remain. Moreover, a gland which undergoes such marked changes in its development and involution may easily have had its balance with the other glands of internal secretion upset a long time before birth, with resulting hyper-adrenalism. This may exist in widely varying degrees and would determine the amount of hypertrophy present at birth. It cannot be claimed that in all cases the hyper-secretion is controlled by changes in the gland itself. The ready response of its secretion to stimuli from the semilunar ganglion would lead one to expect that in some cases there is hyper-adrenalism following excessive stimulation of the splanchnics. Tyrrell Gray and Parsons have shown the effect of excessive stimuli passing to the sympathetics. Their work gives a possible explanation of the added pyloric spasm in the frequently associated condition of phimosi. If the development of the suprarenal gland may be excessive or its involution unduly delayed, one would expect sooner or later to find an abnormally large gland associated with hypertrophy of the pylorus or other non-striated muscle.

Recently there was admitted to Dr. G. F. Still's ward at the Great Ormond Street Hospital a boy aged 8 weeks. Although the mother was ill throughout her pregnancy, the child was born at full term and was apparently healthy. He was breast fed and never gained. He was constipated and had vomited at irregular intervals practically from birth. The mother brought him to hospital because of the vomiting and wasting, and also because of a very distended abdomen. Examination on admission showed marked wasting. The abdomen was too distended to permit of any satisfactory examination, and dilated coils of intestine bulged through the abdominal wall like the rungs of a

ladder. There was stenosis of the urinary meatus and marked phimosis of the type described below—that is, a well-developed penis with the prepuce stretched tightly over the glans. Before the clinical investigation could be completed the child died. At the post-mortem examination rigor mortis had passed off, and the external features as noted above were confirmed. There was stenosis of the œsophageal and pyloric openings of the stomach, and a slight hour-glass constriction about the middle of the viscus. The stenosis was not extreme, but there was definite thickening of the muscle at the pyloric orifice and to a lesser degree at the œsophageal opening. The duodenum and the upper part of the jejunum were contracted and small. From this point down there was a gradual increase in the calibre of the gut, which was considerably dilated in the lower part of the ileum, and the whole colon as far as the junction of the pelvis with the rectal portions. At this point there was another definite constriction. Below this point the bowel again bulged out, to end in a narrowed and constricted anus. The ureters as they entered the bladder appeared small, but the upper two-thirds of both, as well as the pelvis of both kidneys, were dilated. This was obviously a case of early hydronephrosis secondary to a narrowed and constricted urinary outlet. The right suprarenal gland appeared normal, but the left was enlarged to about one-third the size of the kidney.

Sections of the enlarged suprarenal gland were made, and Dr. T. R. Elliott expressed an opinion upon them. He thought the enlargement was entirely confined to accessory cortical cells, and was not of any importance.

The significant feature of this case is that there was stenosis at points in the gastro-intestinal tract other than the pylorus. This would indicate that the influence at work did not emanate from the immediate vicinity of any one of these points, and that the spasm producing the stenosis must have been the result of some general physiological disturbance affecting all the orifices. The only influence we know of from experimental investigation which will cause spasm of the above nature is hyper-adrenalism. There was nothing in the appearance of the gland with which these changes could be associated. The gland evidently proceeded along its normal course of involution, leaving only the results of ante-natal hyper-secretion. It is unjustifiable to insist that hyper-adrenalism is the cause of congenital pyloric hypertrophy, because it cannot be proved. There is, however, sufficient evidence to justify one in holding it to be the most reasonable explanation.

#### *Contributory Causes of Spasm.*

As has been suggested above, the amount of hypertrophy present at birth is insufficient, except in rare instances, to cause symptoms of obstruction. This is clearly evident from the clinical history of the great majority of cases. But there are certain conditions which will cause spasm after birth sufficient to complete the obstruction in an already stenosed orifice. This combination determines the onset and severity of the symptoms. That some of these cases recover without surgical intervention is due to the fact that the subsidiary conditions are amenable to palliative treatment, and are of greater moment in producing obstruction by added spasm than the congenital stenosis itself. And there is sufficient evidence to justify the opinion that the two chief contributory causes of spasm, phimosis and secretory inhibition, are directly associated with the congenital hypertrophy.

1. *Phimosis.*—The association of phimosis is very interesting. That phimosis in itself may cause spasm we know.

In 1914 there were admitted to Dr. W. S. Colman's ward at Great Ormond-street, three baby boys who showed gastric peristalsis and projectile vomiting. No tumour was palpable, therefore no diagnosis of congenital stenosis was made. They were all markedly phimosed, and circumcision permanently relieved the symptoms in all three.

Moreover, in cases of true congenital stenosis circumcision without any other form of treatment has relieved the symptoms immediately for varying periods of time. Further, an analysis of the last 84 cases admitted at Great Ormond-street showed only 13 girls and not one Jew. This in itself is an observation of marked significance as to the association of phimosis with congenital stenosis of the pylorus. Whether it is an associated condition, or the cause of the added spasm, or both, is difficult to say. Certainly it may be a potent cause of spasm. A large majority of boys in this series of cases showed phimosis of a definite character. There is not, as a rule, a long prepuce with a narrow opening covering a small penis, but a prepuce stretched tightly over the glans of a particularly well-developed penis. In other

words, "the penis is too large for the prepuce." Up to the present investigators consider that it is the cortex of the suprarenal gland with which is connected development of the sexual organs. The association of precocious sexual development with malignant hyper-nephromata is in itself significant. It may well be that there is a definite relation between a slow involution of the suprarenal gland and phimosis of this particular type. The way in which phimosis may produce pyloric spasm has been shown by Tyrrell Gray and Parsons, and will be referred to more fully in the joint paper which follows this article.

2. *Secretory inhibition.*—The most important factor in producing added spasm at the pyloric orifice is a secretory disturbance directly attributable to the obstruction. Under normal conditions the acid content of the stomach, passing through the pylorus and over the duodenal mucous membrane, stimulates the formation of secretin. This is absorbed into the blood and is carried to the pancreas, stimulating the formation of the external secretion of this gland. This phenomenon had been investigated by many physiologists, and the correctness of the observation was finally demonstrated by Bayliss and Starling. They also determined that the amount of pancreatic secretion exhibited varied directly with the amount of acid chyme passing through the pylorus. Normally, acid chyme in the stomach opens the pylorus and in the duodenum closes it. In the absence of a sufficient supply of the alkaline pancreatic secretion, the acid chyme is much longer being neutralised. During this time the pylorus remains closed. Given an already stenosed orifice, there is, in the absence of any other cause, a diminished supply of pancreatic secretion. This very lack in secretion will keep the orifice closed, with still less room for stomach contents to escape, and thus still less pancreatic secretion. In this way a vicious circle is set up which effectively obstructs the already narrow stomach outlet. There are several reasons for thinking that there is pancreatic insufficiency. Even under ordinary circumstances clinicians know that babies cannot digest the more complex forms of starches. From this one deduces diminution or absence of certain starch-splitting ferments in the pancreatic secretion. Again, it is a noteworthy fact that babies with congenital pyloric stenosis do better on a diet of pancreatinised milk than on any other food. Moreover, after relief from obstruction either by palliative or by surgical treatment, the child, though fed on peptonised milk, has loose, frequent, greasy stools for several days. This has been noted by several observers, and Still has pointed out the grave danger of "diarrhœa," in the early post-operative period, in those cases where surgical intervention became necessary. These loose, frequent, greasy stools are not the result of any inflammatory charge in the mucosa, but are due to the presence of incompletely digested fats. Still has also noted in these cases that babies tolerate fats in their diet very badly. Even when the obstruction is relieved the child will still do better on a diet of peptonised milk low in fats for the first couple of weeks. The reason suggests itself. A gland like the pancreas, whose function has been inhibited for any length of time by pyloric obstruction, will not resume its maximum function the moment the obstruction is relieved, but will take a corresponding length of time before it secretes sufficient ferments to digest the proteids and fats. Then, again, the small, hard, dry stool so characteristic in these cases is due as much to the lack of secretions as to the small quantity of food passing through the pylorus. Thus there is clinical evidence to show that there is pancreatic insufficiency in cases of congenital stenosis. Add to this the evidence of Sharpey Schafer that the suprarenal gland is antagonistic to the pancreas, and it would seem that hyper-adrenalism, relative or absolute, would inhibit pancreatic secretion. There is then good reason for justifying the assumption of pancreatic insufficiency, which we know is a powerful factor in producing pyloric spasm. Given hyper-adrenalism, there is at once sufficient cause for the primary hypertrophy induced by spasm and for the perpetuation or reinduction of this spasm by pancreatic insufficiency.

#### *Effect of Changes in the Stomach.*

Nothing has been mentioned about the effect on the stenosed pyloric orifice of changes in the stomach itself. Any local irritative conditions or inflammatory changes will, of course, produce swelling of the mucosa. In many of the cases, perhaps all, there is some change of the nature produced by the undue retention, and thus fermentation, of

food. Ordinarily these changes would not cause obstruction, but added to congenital pyloric stenosis, they hasten the formation of the vicious circle, and the perpetuation of the obstruction is due to the more rapid secretory arrest. It is also likely that phimosis, while in itself an important cause of spasm, hastens the appearance of symptoms of obstruction in the same way.

#### *Relation to Treatment.*

The recognition of these phenomena has a most important bearing upon treatment, palliative or surgical. In my joint paper with Mr. H. Tyrrell Gray we have studied the application of this theory to the treatment and indications for operation. The results obtained and the observations we have been able to make justify one in thinking that this theory of the pathogenesis of congenital pyloric stenosis as outlined above is based on sound deductions.

#### *Importance of Internal Secreting Glands in the Study of Diseases of Children.*

The experimental evidence available shows that only one condition will produce spasm of unstriated muscle, and that is hyper-adrenalism. An effort has been made to present to the profession the application of this condition—the result of an ante-natal lack of balance between the internal secretory glands—to the pathogenesis of congenital hypertrophic pyloric stenosis. This study, of course, opens up a very wide field for investigation. If hyper-adrenalism may exist, why not hypo-adrenalism? One may yet have to reconsider the aetiology of the whole question of intestinal stasis from this point of view. Again, Rachford has reported the post-mortem examinations of six children who died from pyloric stenosis where no possible cause of death could be found other than an abnormally large thymus gland. Experimental physiologists have shown that in extirpation of the thyroid gland hypertrophy of the thymus ensues. The thyroid secretion is antagonised by the suprarenal secretion. How far may one go in one's deduction? This fact is clear, we must not study children as young adults. Their physiology is entirely different, and their symptoms should not be measured by similar symptoms in adults. Many of the problems they exhibit must be studied from the developmental point of view, and in this connexion none of their organs are more important, or so easily upset by faulty interaction during the course of their development and involution, than the internal secreting glands.

## CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS:

### ITS DIAGNOSIS AND TREATMENT.

#### A CLINICAL STUDY.

By H. TYRRELL GRAY, M.A., M.C. CANTAB.,  
F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS TO THE WEST LONDON HOSPITAL; SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, TO THE ITALIAN HOSPITAL, AND TO THE INFANTS' HOSPITAL, VINCENT SQUARE; HUNTERIAN PROFESSOR (LATE ARRISS AND GALE LECTURER) R.C.S., ETC.;

AND

GEO. R. PIRIE, M.B. TOR., M.R.C.P. LOND.,

MEDICAL REGISTRAR AND PATHOLOGIST, RESIDENT MEDICAL SUPER-INTENDENT, AND CASUALTY MEDICAL OFFICER FOR THE PERIOD OF THE WAR TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

#### I.—*Diagnosis.*

There are very few diseases of infants in which opinions as to the diagnosis and treatment differ so widely as in congenital hypertrophic stenosis of the pylorus. The mortality is generally so high, indeed so amazingly high, in undoubted cases, that it has led the writers to make a special joint study of this condition for the past few years. One of the first conclusions to which we have been led is that the unsatisfactory results obtained from various lines of treatment advocated are largely to be attributed to the fact that such treatment has been empirical rather than based on a full appreciation of the aetiology; while the extraordinary variability of the figures published by competent authorities is explained by the difficulty of certain diagnosis in doubtful cases, and therefore by the different standards adopted in establishing such a diagnosis in any given case. Thus some observers do not consider the presence or absence of a

palpable tumour an important point in diagnosis, though we place this first and foremost as the most important diagnostic feature.

It must be clear, we think, that the repudiation of such an important point must of necessity lead, in any series, to the inclusion among true and undoubted cases of congenital hypertrophic stenosis of mild or doubtful ones; or even of cases which only resemble the condition under discussion in their clinical manifestations and do not really come into the same category. Such figures are not only useless but misleading. The first point, therefore, to be made quite clear in such a study is the clinical picture on which the diagnosis of congenital hypertrophic stenosis is based. The signs and symptoms upon which such a diagnosis is to be founded are: 1. The presence of a palpable tumour in the region of the pylorus. 2. Visible gastric peristalsis. 3. Projectile vomiting. Associated with these are nearly always varying degrees of: 4. Constipation. 5. Phimosis. As the symptoms in the great majority of cases first appear at a fairly constant period in the child's life some consideration in making a diagnosis must be given to: 6. The age of onset. The general appearance of the child in long-standing cases is characteristic of marasmic children whatever the cause of wasting, and will not be discussed.

1. *A palpable pyloric tumour.*—First in importance in making a diagnosis of true congenital hypertrophic pyloric stenosis is the detection of the tumour. It is the one certain sign. Failure to find the tumour must always leave the diagnosis in grave doubt. It is said that it cannot be demonstrated in every case, but we believe that repeated examinations, with the child under favourable conditions, should reveal its presence. It is usually found just outside the outer border of the right rectus muscle in the trans-pyloric plane. Deep palpation is necessary as it may lie well back, often tucked in beside the vertebræ. Occasionally it is higher, when care must be exercised to exclude Riedl's or an enlarged quadrate lobe of the liver. Sometimes also it is situated lower in the abdomen, in cases where there is extreme gastric dilatation. Often a clue to its situation may be obtained by locating the right limit of the peristaltic waves. When found it gives a very characteristic sensation; it feels like a marble which rolls away from the examining finger as it is touched. Examination of the tumour in the operating and post-mortem rooms has shown that there is considerable variation in its size and appearance. The majority, however, fall into two groups:

(1) *A large hard avascular type.*—At operation this kind appears as a hard, smooth, glistening, oval or cylindrical, white, and almost bloodless, swelling about the size of a large acorn.

(2) *A small hard vascular type.*—In this instance the size is less than the preceding; there are more blood-vessels evident, but otherwise it presents almost the same appearance. This variation in size sometimes accounts for the difficulty in finding it, the smaller ones naturally presenting the greater difficulty. Other reasons for missing it may be:

(a) *Dilatation of the stomach.*—In this case the dilated stomach overlaps the pylorus and makes its detection impossible until the dilatation has been somewhat relieved by palliative treatment.

(b) There is often difficulty in getting the examining finger behind the lower border of the liver and in palpating deeply enough.

(c) *The age of the child.*—In older children of 2 or 3 months the better-developed abdominal muscles increase the difficulty of palpation. Moreover, the coils of intestine are somewhat distended, as they have been functioning longer.

The most favourable time for examination is while the child is being fed. The food when it reaches the stomach drags on the fundus and uncovers the pylorus. Moreover, the peristalsis induced by the presence of food in the stomach makes it more apparent. Sometimes it is necessary to postpone the examination until after repeated lavage, when the dilatation is sufficiently relieved to permit of easier palpation. Where difficulty with the liver or a deeply-placed pylorus is encountered it is a good plan to turn the baby on its face, allowing the slightly flexed body to rest on the palm of the hand. In this position the abdominal walls are more relaxed, and the child cannot resist examination as much. The viscera fall forward, and the fingers can be more easily pressed behind the liver and explore the whole region. The examination should always be made with the thoroughly warmed left hand from the left side of the patient.

2. *Visible gastric peristalsis.*—This is evidence that the tumour, palpated as above, is sufficient to cause a marked degree of obstruction at the outlet of the stomach. By itself it is not of paramount importance. In Case 14 no peristalsis was seen until the child was on the operating table under deep anaesthesia, although it was believed that the tumour had previously been palpated. On the other hand, pure spasm without congenital hypertrophy may cause gastric peristalsis and projectile vomiting. The following case illustrates the point:—

A boy (Case 18), age nine weeks, was admitted to the hospital. Visible gastric peristalsis and projectile vomiting were demonstrated, and the child was markedly wasted. There was also a very tight phimosi. No tumour was palpated, therefore no diagnosis of congenital stenosis was made. The only treatment carried out was that of circumcision. Subsequent to this operation there was no more peristalsis seen, nor did the child vomit again. Some 60 hours later he suddenly collapsed and died. Post-mortem examination showed considerable dilatation of the stomach, but no abnormal thickening of the pyloric muscle whatever.

The three cases admitted under Dr. Colman, mentioned in the previous paper (G.R.P.), also show that gastric peristalsis may be visible without congenital stenosis. If this sign is not obvious it can often be elicited by gently stroking the epigastrium or by giving a feed.

3. *Projectile vomiting.*—This symptom is of similar diagnostic importance to visible gastric peristalsis. When characteristic, the food is forcibly ejected across the cot on to the floor, and will also appear streaming from the nostrils. Usually the baby is not otherwise disturbed, and appears quite happy about it. It may occur after every feed, or at infrequent intervals. Sometimes the food is returned before the child has finished suckling, and at other times one or two hours later. The character of the vomits will, of course, depend on how long the food has remained in the stomach, but it is never bile-stained. Infrequent vomiting must not always be regarded favourably, because, with increasing dilatation of the stomach, two or more feeds may be retained before the whole is ejected. This will account for the frequent history that the child "vomits more than it takes." The vomiting is not always projectile. Under palliative treatment it may become much less forcible if no less frequent. As has been shown above, it may occur also where there is no congenital stenosis.

These are the three cardinal features to be considered in making a diagnosis. Taken together, their presence will indicate congenital hypertrophic stenosis with a high degree of obstruction. Taken separately, the first only is of paramount importance. There is sufficient evidence to show that the other two may occur where pylorospasm exists alone. There is a great variation in the published statistics of this condition. Many observers have reported brilliant results in long series of cases under medical treatment. From the above conclusions we consider that, in many such instances, the diagnosis has been made on entirely insufficient grounds, and that the number of cases of true congenital pyloric stenosis is but a fraction of those reported. A positive diagnosis may never be made without finding the pyloric tumour.

4. *Constipation.*—This is usually marked. In typical instances the motions are small, hard, and infrequent. Its relation to the primary condition is evident. If very little food passes the pylorus there will remain even less to be evacuated. Reference has been made in the previous paper to the associated secretory inhibition. This lack of secretion explains the hard consistence of the stool. The diagnostic importance rests on the fact that the size of the stool will, in a measure, indicate the degree of obstruction at the outlet of the stomach, while its consistence will indicate the degree of secretory inhibition.

5. *Phimosi.*—In males phimosi, or an adherent prepuce, is constantly associated with congenital pyloric stenosis. Its frequency, character, and possible relation to the primary condition have been dealt with in the previous paper. That marked phimosi may be sufficient to produce pylorospasm reflexly is evident from the cases reported above and subsequently.

It has been shown<sup>1</sup> how definitely a powerful afferent stimulus, in its efferent response, not only involves the sympathetic system as a whole, but does so particularly in

the splanchnic system, and that such an efferent response in the splanchnic system not only involves the vascular distribution of the sympathetic, but also its intestinal muscular supply. Thus, it was pointed out that a reflex, acting both through the higher centres and also through the segments involved, might induce a powerful stimulus resulting in an inhibition of the intestinal muscle. The sphincters in the intestinal tract, however (i.e., pyloric and ileo-caecal), appear to have an inverse innervation, so that a stimulus which inhibits the bowel musculature causes a contraction of the sphincters. The powerful afferent stimulus arising from the prepuce is well known, and it is not difficult to appreciate that the constant series of small stimuli arising from the prepuce in a subject of phimosi may well induce, in this way, a spasm of the pylorus. It is possible that such a spasm may arise either from direct nerve stimulation or from excessive stimulation of the suprarenal hormone, or from both of these.

6. *Age of onset.*—The age at which these babies are usually brought for advice is from four to eight weeks. We are then told that the vomiting and wasting have gone on for from one to five weeks. So that the symptoms, in the great majority of cases, appear about the third week. Occasionally one does not see the child until, perhaps, the third month, and true cases have been reported as showing symptoms from the third month only. These cases are sometimes not easy to diagnose because of the difficulties in physical examination mentioned above.

On rare occasions examination under an anaesthetic may be necessary before a diagnosis can be made.

A history of projectile vomiting beginning about the third week, which is unrelieved by the ordinary methods of treatment, is highly suggestive, and should lead to a detailed examination in respect of the above signs and symptoms. Then an opinion can be formed as to whether the condition is one of pylorospasm or congenital hypertrophic pyloric stenosis.

## II.—Sex Incidence.

It is a remarkable fact that all published statistics show a very large preponderance of boys. In the series we quote, of 84 cases, there were only 13 girls. The male, being vagotonic, might be expected to show spasm sufficient to cause hypertrophy more often than the sympathetico-tonic female. But this cannot account for the total difference. Certainly girls do suffer from congenital stenosis, but we are able to show their behaviour to be different. They are slower developing the characteristic symptoms of obstruction, and therefore usually come under observation at a somewhat later age. (Vide Cases 4, 14, and 15.) That they will also show a correspondingly slower recovery than boys is particularly well illustrated by Cases 14 and 15. These cases will be referred to again in more detail, when these factors will be emphasised.

As has been stated previously, thickening of the pylorus has been noted in many post-mortem examinations of children, both male and female, who showed no symptoms of obstruction during life. It was also shown that the incidence of these symptoms depended upon the relationship existing between the degree of congenital hypertrophy and the severity of the added spasm. In girls the more urgent cause of spasm—phimosi—does not exist.

We are thus led to believe that many children, boys and girls, are born with some degree of pyloric hypertrophy who never develop pyloric obstruction. And we conclude that the sex difference is more apparent than real. That is to say, apart from the slight excess in the number of males, possibly due to their vago-tonicity, the sex incidence is about equal.

It would be interesting to know the relative number of boys and girls in Jewish children who develop pyloric obstruction. Our deductions from the present study would lead us to expect that, in Jewish subjects of pyloric hypertrophy, clinical symptoms of obstruction would be manifested in as many girls as boys. Further, that progress would be identical in both sexes under palliative or operative treatment.

## III.—Operative Treatment.

*Criticism of operative procedures.*—In estimating at their value the effects of different forms of treatment in a particular disease there are several factors which are essential to a sound judgment. Foremost amongst these is the necessity for every case to be studied under conditions of

<sup>1</sup> Tyrrell Gray and Parsons, Arris and Gale Lectures, Roy. Coll. Surg., 1912.

medical attention, after treatment, nursing, housing, temperature, &c., as nearly constant as possible. Only under such conditions can the vitiation of results by outside influences be excluded, and the intrinsic value of any operation be accurately estimated. For this reason the value of this study would be much diminished if it included cases seen in a number of other hospitals as well as in private practice, since such a lack of uniformity would prejudice the value of observations intended to support or disprove a definite hypothesis. It is well known that, up to the present, the results of surgical treatment of congenital hypertrophic stenosis are markedly inferior in hospital to private practice, whatever operation may be performed. Thus we can record successes both with Loreta's operation (divulsion), and with gastro-enterostomy in apparently hopeless cases, in private practice, when undivided individual attention and every possible facility were available. But at Great Ormond-street, up to April, 1918, when we first initiated the Rammstedt operation as a routine procedure, there had never been a single instance of recovery after surgical intervention. A second feature of importance in ascertaining the best surgical procedure, and the indications for its adoption, is that different methods should be given a trial by the same surgeon; for the fact that one surgeon obtains the best results with one particular operation, while another similarly perfects himself by practice with a different one, from which he deduces his figures, is of limited value in helping the profession to judge which method is to be generally adopted as the most hopeful. In order, therefore, to arrive at impartial results we have practised for the last few years three kinds of operation: (1) gastro-enterostomy, (2) Loreta's operation, (3) Rammstedt's operation. It is feared that the number of cases available is not large, because surgical results have been so unsatisfactory that it has been difficult to get physicians to allow cases to be operated upon; while, on other occasions, when the surgeon has been called in, their condition has been such that surgery has rarely been afforded a fair trial.

However, since the same disadvantages obtained when the operation of Rammstedt was first practised, the comparison of results in these three procedures is tolerably fair. The first point of importance, then, is the decision as to which variety of operation is the best and based on the soundest principles.

Pyloroplasty will not be discussed, because, though it may be possible to do this operation successfully in a limited number of cases, it is only necessary to see and feel some of the hard, almost cartilaginous, tumours so often met with, to appreciate the fact that the adoption of any plastic method is impossible with any degree of certainty or security.

The operation of Loreta, though it has been attended with such a great measure of success in the hands of Mr. F. F. Burghard, has disadvantages which cannot be ignored. In the first place, this procedure is unsound in principle because it lacks precision. Thus the object is to rupture the hypertrophied and spastic circular fibres without damage to the mucous membrane, and, if possible, without rupturing the peritoneal coat. That this object is attained only by violent measures is true, however carefully and slowly the dilators are introduced, and whatever length of time is allowed to elapse while each dilator rests in the pylorus before the next size is employed. Secondly, it is not always a simple matter to gauge the exact amount of dilatation required to rupture the muscular coat, though, when rupture has occurred, the gap can usually be felt with the fingers of the left hand as they grasp the pylorus during these manipulations. It is easy to avoid damage to the mucous membrane; indeed, with the most ordinary precautions, it is impossible to do harm in this way. There is no certainty at any time that the peritoneum will not split when the muscular coat gives way, for it is so thin, friable, and adherent to the tumour that, in many instances, the rupture of both may take place simultaneously. Thirdly, this very lack of precision leads to overstretching or to insufficient stretching, leaving to the surgeon's instinct and experience alone the estimation of the amount required. Recurrences of obstruction in the latter eventuality are to be expected. In the absence of full statistics no estimate of the percentage of recurrences can be given, but it does undoubtedly occur. Fourthly, such an operation on an obstructed stomach is more liable to be a septic one on account of the retained contents and consequent changes in the gastric

mucosa, since the stomach has to be opened in order to introduce dilators; and a certain amount of infection, however mild, must add to the severity of the operation in so small a subject, in spite of every care to avoid soiling. Fifthly, the operation cannot be performed carefully and gently in less than 15 minutes, most of the time being consumed in allowing each dilator to rest a short time in the pylorus as larger sizes are used. Such a length of time in an operation of violence on a young subject, together with the addition of the necessary sepsis entailed by opening the stomach, combine to make the operation a severe one. Sixthly, the exact site of the rupture can never be predicted with certainty.

It follows naturally that Loreta's operation is only available for early cases, when the nature of the condition is established soon after the onset of symptoms, and before the baby is markedly wasted. In later cases, when the subject is wizened and marantic, or almost moribund from loss of fluid, this operation is doomed to failure and cannot be advocated generally as a means of saving life. Now we submit that any operation of the severity and risk entailed in the surgical treatment of so dangerous a condition should, if the immediate operation risks are survived, at least be one that offers a certain cure with no risk of recurrence. This cannot be claimed, we believe, from Loreta's operation. Further, it must be practised on early cases of fair physique to offer a reasonable chance of success. If this principle be adopted as a routine, we believe that, though a definite proportion of cases will be operated upon successfully, in accordance with ordinary surgical risks, even favourable cases will sometimes succumb to Loreta's operation. Amongst these will be numbered a certain proportion who would have recovered by palliative measures alone. For these reasons we are of opinion that the ideal operation to be advocated generally is one which offers the chance of a certain cure, while being applicable to cases in which palliative treatment has been given a trial and failed. It is from this standpoint that we have made a study of congenital pyloric stenosis. In following this study we would ask our readers to bear in mind that, in every instance, operations have been performed only on infants with whom palliative measures had definitely failed and the child was losing ground. In no instances have operations been performed without giving such preliminary measures a fair chance. Further, we emphasise the fact that, had we been aiming at good statistics alone, many cases would not have been operated upon; and still further, that in no single instance has operation been declined owing to the feebleness of the subject. As a result life has been saved on more than one occasion in an apparently hopeless case, though naturally our actual figures suffer.

(1) *Gastro-enterostomy*.—The obvious drawbacks in Loreta's operation led us to try gastro-enterostomy as an alternative method. Successful gastro-enterostomy has, at least, the merit of certain cure. This operation was attended in the past with such a high mortality that, by common consent, it had been abandoned as a routine method. But we wished to try this method under spinal anaesthesia. The number of cases is too small to allow of statistical deductions, but the reasons for the abandonment of this procedure are of importance. Briefly, gastro-enterostomy has been performed on four cases; three were operated upon under spinal anaesthesia and one under warm ether anaesthesia. The posterior no-loop operation was performed on all the cases. Two were operated on at Great Ormond-street and both died within 48 hours. Two were operated on elsewhere and both recovered. One of these, in excellent condition, with no adverse symptoms after the operation, developed a fatal pneumococcal meningitis, by extension from the middle ear, about a fortnight later. The other was alive and well some few months ago, three and a half years after operation. There can be no doubt that spinal anaesthesia improves the outlook from this operation, which can be performed easily and securely in a total time of 15-20 minutes. With figures showing 50 per cent. recoveries in all cases, it might appear that there was no justification for abandoning this procedure. The figures, however, do not represent the whole case, and the reasons for discarding gastro-enterostomy are as follows.

The two most favourable cases were those at Great Ormond-street, where everything appeared in favour of recovery, yet both died. Of the two babies who recovered, one appeared practically moribund, the other seemed

hopelessly wasted and feeble; both owe their recovery to the most constant devotion and attention of doctor and nurse, and even so their condition was quite critical for some days. Again, though the operation can be quietly and gently performed under favourable conditions in 15 minutes, this end will only be attained by perfect team work between anaesthetist, sister, assistant, and surgeon, and allows no margin for surgical accidents, small delays, &c., and the hundred-and-one small events which contribute towards, or militate against, a smooth and rapid operation. Finally, even when everything has gone perfectly, without a hitch, the child's condition immediately afterwards is always bound to be critical; while, in the presence of any adverse circumstances, a fatal result is almost sure. It was concluded, therefore, that though many recoveries might be obtained with gastro-enterostomy, even in late cases, there would always be too great an element of "luck," and the prognosis must always be too doubtful to justify its routine adoption. There is another point which deserves mention. It has been shown in a post-mortem performed on one of these cases many months after gastro-enterostomy (death had occurred from other causes) that, though symptoms are definitely cured and the child is apparently normal in every respect, the pyloric tumour remains. In other words, gastro-enterostomy does not cure the congenital hypertrophy of the pylorus, but only short-circuits the site of obstruction. (Vide Rammstedt's operation (3).) Finally, since the aim of any operation should be, if possible, directed primarily at the cause of the evil, we trust that our study will show that gastro-enterostomy is a measure which aims only at circumventing the gastric obstruction, and does not attack the origin of such obstruction. It is a little difficult to account for the inferior immediate results obtained by gastro-enterostomy compared with those following Loreta's operation, for the time taken by this operation is no longer (indeed, it is often shorter); while the operation itself is of a gentler nature involving less manipulation. Nevertheless, it seemed clear that, in spite of the apparent certainty of cure, gastro-enterostomy ought to be abandoned as a routine method. Loreta's operation was therefore reverted to in cases where palliative treatment had definitely failed.

(2) *Loreta's operation.*—This operation has been performed on four occasions at Great Ormond-street; all were fatal. We record a total of 7 cases with one recovery. In all cases a feed was introduced into the duodenum as recommended by Mr. Burghard. The first two cases were operated upon under spinal anaesthesia, one male and one female; both were 6 weeks old; both died. In one of them the child did well for 11 days and gained 4 ounces in weight, and then commenced to go downhill and began to vomit. Subsequent to operation visible peristalsis was never seen. In the other case no cause of death is stated in the notes; but it may be stated that spinal anaesthesia was abandoned in these very wasted and feeble infants, owing to the frequency of massive collapse of the lungs to which there is a great liability. Of the other two infants who died after Loreta's operation, one is of special interest.

The child was a male of 4 months, in whom vomiting commenced at 2½ months. It was a weakly infant of 6½ lb. Loreta's operation was performed under open ether anaesthesia and lasted under 15 minutes. The muscular coat was ruptured by a No. 10 Hegar's dilator, which was left in situ for a few seconds. The pulse remained excellent throughout, but breathing became spasmodic during the dilatation, and continued so for some time after returning to the ward. There was an occasional vomit during the first few days, but the child's condition improved for the first 13 days, with a gratifying gain in weight. (Chart 1.) Diarrhoea and vomiting supervened, and though this was controlled at times the child gradually sank and died one month after the operation.

The two features to be noted in connexion with this case are:

(a) The spasmodic breathing inaugurated by the dilatation of the pylorus. (b) The occurrence of vomiting after the operation.

(a) The first of these two has been noted by us on several occasions during Loreta's operation, and is attributable, we think, to a violent afferent vagus stimulus initiated by the violent stretching (and persisting for some time afterwards), which inhibits inspiration in much the same way as a "blow in the wind."

(b) The occurrence of vomiting after Loreta's operation was noted in all three cases which recovered from the

operation. Four cases definitely died from the operation, while two died within a month, as already detailed. One case recovered and is alive to-day. In the last three cases vomiting was noted after operation; it was not forcible in character, and visible peristalsis was not present. This feature is, we think, to be explained by the fact that, though the circular muscular coat is completely ruptured by the

CHART 1.

The arrow indicates the day of operation.

passage of the dilators, this manipulation induces a swelling and hyperaemia of the mucosa which partially closes the pylorus until this new factor subsides. It is not due to insufficient dilatation, for in each case the split in the muscle was definitely felt, and there were no signs of gastric obstruction such as could be observed before operation, while the vomiting was in no instance of a projectile character. We have, of course, too few cases to allow us to say how often this feature is to be noted after Loreta's operation; but, in view of our small experience, we should expect it to be fairly common.

The one case which recovered was of considerable interest in that it was due to this experience that Loreta's was abandoned in favour of Rammstedt's operation. In this case, during the final dilatation, the muscular and peritoneal coats were both split over a distance of about half an inch. The gap was closed by a catgut stitch, since any attempt at invagination was out of the question, owing to the hard and cartilaginous nature of the tumour. Contrary to expectation, the child made a good recovery, and it was this fact which overcame a natural disinclination to divide these two coats of the pylorus deliberately from the outside and leave them open with the mucous membrane exposed.

(3) *Rammstedt's operation.*—This operation aims at the relief of the pyloric obstruction without at any time opening the gastric mucous membrane. This procedure seems to have been adopted with success by Rammstedt, whose name is attached to the operation, in 1913. The credit, however, for devising a method of relieving the obstruction without opening the gastric mucosa must, we think, be given to an Englishman, Mr. Russell Coombe, of Exeter. This surgeon published a recovery in 1911 (Annals of Surgery) by an extra-mucous pyloroplasty, and in the same paper suggested a modification (which has since been practised with success) designed to facilitate the introduction of the necessary sutures. Rammstedt's operation surpasses in speed, simplicity, and certainty every other operation for the relief of hypertrophic pyloric stenosis, by eliminating every unessential detail. The essential principle of the operation is the recognition of the fact that the mucous membrane of the pylorus is sufficiently thick and redundant to provide by itself adequate protection for the peritoneum against leakage and infection from the gastric contents. The realisation of this all-important fact naturally suggests the simplest of all measures for the relief of the obstruction—namely, the longitudinal division of the hypertrophied

pylorus down to mucous membrane; this constitutes Rammstedt's operation. It might appear that such a simple operation offers, in its actual performance, little for the surgeon to learn; but experience has shown that this is not the case, and this study will serve a more useful purpose if we briefly describe some of the points of interest in the cases on which this operation has been performed. We have performed Rammstedt's operation on 17 occasions at Great Ormond-street, with seven deaths and ten recoveries, giving a mortality of 41.1 per cent. Two facts must be noted:—

- 1. Pre- and post-operative treatment has been practically identical in all cases.
- 2. In no instance have we declined operation on account of the bad condition of the patient, whatever the reason. In other words, every case, without exception, when palliative measures definitely failed, was afforded the chance of a cure by operation.

CASE 1.—M. Age 9 weeks. Symptoms present for four weeks. The child rapidly went downhill, and vomiting increased until at the time of admission the description is that of a very wasted baby, with drawn face, lying with eyes and mouth half open, fontanelle depressed, presenting classical symptoms and signs of hypertrophic pyloric stenosis. In spite of infusion, the child when first seen was grey and semi-conscious, with slow intermittent gasping respirations, for which it was placed in a mustard bath. Operation was temporarily declined unless improvement took place with subcutaneous infusion of saline and 2 per cent. glucose. This was continued for 36 hours, when it was considered that operation offered a faint chance of recovery. As it was thought that any of the more recognised operations offered little hope of success, Rammstedt's operation was performed for the first time. At the first incision the skin and subcutaneous tissues were oedematous with saline which oozed as if a local anæsthetic had been given, while, on opening the peritoneum, fluid poured out as in a case of ascites. The pylorus was brought up into the wound and an incision rapidly made through the hypertrophied area through all coats down to the mucosa. The pylorus was then returned to the abdominal cavity and the wound closed in layers. Temperature rose to 105° F. the same evening, but commenced to fall rapidly the following day. This child, though apparently quite a hopeless case, made an uninterrupted recovery. There was no post-operative vomiting. Loose motions were noted for a short time after operation. (Chart 2.)

CHART 2.

The arrow indicates the day of operation.

CASE 2.—M. Age 8 weeks. Symptoms started at 3 weeks. This case was booked for operation on the same afternoon as Case 1. Loreta's operation had been contemplated, but the simplicity and rapidity of the Rammstedt was so inviting that it was performed on this case also. In spite of the fact that medical treatment had been persisted in for over three weeks, with no relief of projectile vomits, the condition of the child was much better than in Case 1. The temperature rose to 104° the evening of the operation,

falling to 100° the following day. Recovery was uninterrupted and there was a small vomit on the ninth and another on the tenth day after operation. Loose motions were noted occasionally for the first 11 days.

CASE 3.—M. Age 8 weeks. Symptoms commenced at 5 weeks. Medical treatment for a fortnight, when vomiting became more frequent and 14 oz. in weight had been lost. Incidentally the temperature rose to 102° on the seventh day.

CHART 3.

The arrow indicates the day of operation.

or a week previous to operation. Rammstedt's operation was followed by an uninterrupted recovery. Temperature rose to 105° on the evening after operation. There was one vomit on the second day. Stools were formed on the tenth day, when there were seven loose motions, which improved with a rectal wash-out, and a steady gain in weight supervened. (Chart 3.)

CASE 4.—F. Age 8 weeks. Symptoms commenced at 5 weeks. Rammstedt's operation performed the day after admission. Uninterrupted recovery. The points to note in this case are the frequency of stools the two days before operation and the absence of "diarrhoea" after operation. This observation has a bearing on the different behaviour of girls, to which reference is made later. Post-operative temperature only rose to 101.4°, but it is worthy of remark that in this case the pre-operative temperature showed a variation of 97° to 98.8°. (Vide Case 3.)

CASE 5.—M. Age 8 weeks. Symptoms started at 5 weeks. Baby wasted and had lost much fluid; skin loose and inelastic. Rammstedt's operation was well borne and recovered from, and feeds were well taken. Gastric lavage the evening after operation showed a quantity of undigested milk and mucus. Forty-eight hours after operation the child developed some abdominal pain, and died suddenly an hour later. Post-mortem examination showed that the incision into the hypertrophied part of the pylorus had not been continued sufficiently far on the stomach side—in other words, the incision had been deep enough to sever all coats down to the mucosa, but had not completely divided all the hypertrophied portion in the most important situation. The lesson to be learned from this case, therefore, was that the hypertrophied portion must be divided throughout its whole length down to the mucous membrane. This seemed to be essential to the complete relief of the gastric obstruction; for, though the child was in good condition after the operation, the presence of mucus and undigested milk in the stomach shows that the obstruction was not completely relieved.

CASE 6.—M. Age 6 weeks. Symptoms dated from first week, becoming typical at 3 weeks, and culminating in frequent projectile vomits. Rammstedt's operation performed two days after admission, during which time the temperature varied from 97.4° to 99° and 101°. Recovery was uninterrupted and there was no vomiting. The temperature rose to 104° on the evening of operation, and to 105° on the following day, falling to normal three days later. "Diarrhoea" was noted on the second day. Steady gain in weight was noted from the fifteenth day.

CASE 7.—M. Age 6 weeks. Premature baby born at 7½ months and weighing 5½ lb. Child very feeble and weak. Symptoms dated from nine days ago, and were severe in character. Medical treatment for 17 days with no improvement. Rammstedt's operation was followed by death the same evening.

CASE 8.—This case is of special interest in view of the lesson learnt from a study of the result. M. Age 5 weeks. In good condition. Medical treatment for five days yielded no improvement in the vomiting, while the child steadily lost ground. Rammstedt's operation was performed on the seventh day after admission. The temperature rose to  $102.8^{\circ}$  on the day following operation, and showed from that time the usual steady fall up to the third morning. On the third afternoon the temperature rose again to  $102^{\circ}$ , and was accompanied by five vomits. Subsequent to this diarrhoea and rapid respirations developed; the temperature rose to  $104^{\circ}$ , and the child died at midnight, or nearly four days after operation.

*Commentary.*—Now the interest in, and instruction from, this case lie in the following facts: In Case 5 the obstruction was insufficiently relieved owing to the imperfect division of the pylorus on the stomach side. In the subsequent cases, therefore, special efforts were made to ensure that the division should be complete; and in this case (Case 8) the incision was carried too far down towards the first part of the duodenum. The mucous membrane was punctured at the lowest part of the incision, and had to be closed by sutures. The child did well for three days, when leakage occurred and was followed by death. Post-mortem examination showed that leakage and peritonitis were the cause of death. (At this point in our experience the same incident occurred in private practice. Fortunately, however, in this case the wound in the mucosa was more securely closed, no leakage occurred, and the child recovered.)

#### *Lessons Learned from Cases.*

The lessons we learned from these cases were as follows:—

1. The mucous membrane beneath the hypertrophied pylorus is not only redundant, but is also very thick, and loosely connected with the muscular coat. It is this anatomical fact which renders it so easy to divide the two external coats without damaging the mucous coat over the obviously hypertrophied portion. The mucous membrane under the muscular coat of the stomach immediately adjoining the hypertrophied pylorus is also loosely attached; and it is easy, therefore, to divide well into normal stomach wall without fear of injury to the mucosa or of subsequent leakage. On the duodenal side, however, the mucosa is not only very thin, but it is firmly attached to the muscular coat, so that any prolongation of the incision below the hypertrophied portion is almost certain to wound the normal mucosa of the first part of the duodenum.

2. We also learned that the hypertrophy ends abruptly on the duodenal side in a peculiar manner, but on the gastric side it merges gently into the normal structures.

The peculiar configuration of the hypertrophied pylorus in the duodenal portion is of the highest importance. Thus, there are three features to be noted by the operator.

(1) The mucous membrane is firmly adherent to, and very thin and friable over, the terminal hypertrophied muscular coat at *a*. (Fig. 1.)

FIG. 1.

(2) This terminal hypertrophy projects into the lumen of the duodenum, and the adherent mucous membrane bends back with it towards the stomach to join the normal duodenal wall, where it is also firmly attached at *b*.

(3) It is clear that to divide the hypertrophy completely on the duodenal side as far as *a*, the incision must be carried as far as *c*. But it is equally evident that this cannot be done without just traversing the lumen of the duodenum. The impossibility of complete division of the hypertrophied portion of the pylorus by Rammstedt's operation might, at first sight, appear to constitute an important point in favour of Loreta's method; such a conclusion is unjustified. For not only is the final obstruction due to spasm at the gastric end (and not at the duodenal end) of the pylorus, but the thin and elastic duodenal wall in itself allows too much play for mechanical obstruction to occur at

this outlet. Thus the hypertrophied distal portion cannot and does not form an element in the obstruction, and there is no need for the division to be carried to its termination. The practical lesson, therefore, was that the incision must be carried well beyond the hypertrophied pylorus on the stomach side where the main responsibility for the obstruction lies; while, on the duodenal side, it does not matter very much if the division is a little incomplete, since the main obstruction is not at this situation. Moreover, in the post-mortem room it can be demonstrated that water can be forced from the duodenum through the hypertrophied pylorus into the stomach, but not in the reverse direction. In subsequent cases, therefore, the stomach side has been given special attention; and the landmark adopted for determining the upper limits of the incision was the point at which (1) the muscular coat becomes thin, (2) the muscular coat becomes vascular. In other words, we now make a point of ensuring that the incision stops exactly at a point where venous oozing commences. On the duodenal side we stop just short of the point where the white avascular coat merges into the normal vascular structures of the duodenum. In all subsequent cases these lessons, learned from disappointing experience, have been faithfully applied. The practical justification of these deductions becomes increasingly evident.

CASE 9.—M. Age 7 weeks. Symptoms commenced at 3 weeks. Medical treatment for five days produced some improvement in symptoms for a day or so, but subsequently the child became rapidly worse. Rammstedt's operation was followed by slow recovery, the delay being attributable to the sloughing of the skin at the site of one of the subcutaneous saline injections. Temperature rose to  $104^{\circ}$  in the evening of the operation, but fell to  $99^{\circ}$  the following morning. No vomiting from the day following operation, but "some diarrhoea" was noted for the first ten days.

CASES 10 and 11.—These two cases may be dismissed shortly as offering no basis for study. Both were submitted to Rammstedt's operation, as they were going downhill under medical treatment. Both were operated upon on the same day, during the persistence of influenzal bronchitis. It may be questioned whether these two children were given the best chance of recovery by operating under such adverse conditions, but after careful consideration we decided that the pyloric stenosis was the greater menace and acted accordingly. Had we been considering statistics only we should have refused to operate in both instances. Both cases ended fatally from purulent bronchitis, as evidenced by post-mortem examination, while the abdomen in each instance showed nothing abnormal. We propose, therefore (as we think we are justly entitled to do so), to exclude these two cases from our study.

CASE 12.—M. Age 4 weeks. Symptoms dated from 2 weeks. Medical treatment for eight days resulted in a steady loss of weight of 5 oz. Rammstedt's operation was performed on the eighth day after admission. The temperature rose to  $103.4^{\circ}$  on the day after operation, when the gradual fall was interrupted by repeated convulsions, cyanosis, and rigidity, ending in death three days after operation. There was no post-operative vomiting, while the child bore the operation excellently, and subsequently took its feeds well. Post-mortem examination revealed nothing abnormal. In fact, this case is one of the only two instances in our series in which a fatal result cannot be explained satisfactorily.

CASE 13.—M. Age 4 weeks. Symptoms dated from 3 weeks. Medical treatment persisted in for eight days without improvement. The child weighed 8 lb. at 3 weeks and 6 lb. 6 oz. at the time of operation. Rammstedt's operation was followed by uninterrupted recovery. Post-operative temperature rose to  $105.2^{\circ}$ , but fell gradually to normal on the third day. There was no vomiting after the first day.

CASE 14.—This case presented features of unusual interest. F. Age 3 months. Full-time child, weighing 8 lb. at birth. Vomits started a few days after birth and gradually got larger, more frequent, and more forcible. Child was admitted to Great Ormond-street at 3 months of age. The abdomen was always distended; the pylorus could never be felt with certainty, and we were never able to see gastric peristalsis. A series of X ray examinations after the taking of himuth, carried out on two occasions, showed that a small quantity of himuth escaped through the pylorus soon after it was taken, but that, after this small quantity had passed, the rest remained in the stomach for 48 hours (after which the examination ceased). Vomiting persisted in spite of medical treatment carried out for a month, during which time the child steadily lost ground. In spite of

almost daily infusions of saline and glucose the weight fell from 7 lb. 8 oz. to 6 lb. 4 oz. Rammstedt's operation was performed and was followed by immediate improvement in the symptoms, while a return to the normal and progressive gain of weight was slow and delayed for some weeks, and was characterised by fatty stools for a considerable time. The temperature after operation rose to 105.2° on the second day, falling to normal on the fourth day. There was no frequency of stools and no vomiting subsequent to operation. One point of interest in this case consists in the fact that, though under the most careful and constant supervision for a month previous to operation, the pylorus could never be felt with certainty and we never succeeded in seeing peristalsis, yet directly the child was anaesthetised for operation peristalsis was clearly present to a marked degree.

#### *Effect of Anaesthetic.*

We have already suggested that powerful or constantly recurring afferent stimuli evoke an efferent sympathetic response, and have pointed out that the splanchnic nerves share in this phenomenon to a marked extent. The result of such impulses is, therefore, a corresponding stimulation of the splanchnic nerves, with two main results so far as this study is concerned.

(a) Direct stimulation to contraction (i.e., spasm) of the pyloric sphincter.

(b) A corresponding excess of absorption of suprarenal secretion into the blood, with an accompanying increase in pyloric spasm. The increased contraction of the pylorus is not only accentuated with peristalsis, but such a contracted pylorus is rendered more easily palpable. In this case the stimulus of the anaesthetic, aided by the relaxation of the abdominal walls, seems to be the explanation of this phenomenon. Support is lent to this explanation by the frequency with which early anaesthesia induces visible gastric peristalsis.

CASE 15.—F. Age 11 weeks. Breast-fed, started vomiting at 2 weeks. Brought up to hospital at 4 weeks. Kept on the breast with daily lavage, and, as there was no improvement, supplementary feeds were given. Patient showed a steady but slow loss of weight for eight weeks on medical treatment. Rammstedt's operation performed on admission, pituitrin mxx. being administered previous to operation. Recovery uninterrupted, but progress slow. Temperature rose to 104° after operation, and fell to normal on the third day. No post-operative vomiting and no diarrhoea. This child was in excellent condition before operation and remained so afterwards. The subsequent history of this case is interesting. Peptonised milk was given until the twelfth day, during which time the weight fluctuated round a fairly even figure. Subsequently citrated milk was substituted, with the result that 5 oz. in weight was lost in four days. A steady increase in weight immediately followed the return to feeds of peptonised milk.

CASE 16.—M. Age 6 weeks. Brought to surgical out-patients because of difficulty in passing water, and sickness. Onset sudden at 4 weeks. Projectile vomiting, visible peristalsis, a palpable tumour, and constipation completed the picture; while phimosis (of the type referred to) was well exemplified. Circumcision two days later was followed by a cessation of projectile vomiting, and the passage of copious greasy stools. Loss of weight ceased on the fourth day, and symptoms continued to be relieved until the ninth day, when the recurrence of projectile vomiting demanded radical treatment. Rammstedt's operation was followed by immediate relief of all symptoms, and the passage again of copious fatty stools. There was no post-operative vomiting. Points worthy of comment are:—(1) This was the largest pylorus on which we have ever operated; (2) there was a gain in weight of 11 oz. in the first six days.

These points indicate:—(1) That the infant was born with a pyloric hypertrophy so excessive that the orifice was nearly closed; (2) the deciding factor in the final closure was the added spasm from phimosis which induced a very mild degree of secretory inhibition; (3) circumcision relieved the added spasm to some extent, but not sufficiently to re-establish normal conditions, owing to the excessive hypertrophy.

Briefly, the congenital hypertrophy was the preponderating feature, and therefore the case was only amenable to radical treatment. The fact that secretory inhibition played a small part is evidenced by the immediate post-operative gain in weight.

CASE 17.—M. Age 5 weeks. A very poor, weakly, wasted infant with classical symptoms. Vomiting began about the twenty-fifth day. Phimosis was well marked and of the usual type. Circumcision was followed by no improvement in the symptoms in three days. As the child had no reserve

power to draw upon, and added spasm was clearly playing a minor rôle in the obstruction, we did not wait longer, but decided on operation. Rammstedt's operation was followed by immediate relief of vomiting and the passage of the usual loose, fatty stools. The pylorus was exceedingly large. There was no post-operative vomiting after 12 hours, and the child's condition continued to improve daily. Sudden death from unexplained causes on the fifth day surprised everyone. Post-mortem examination of a most detailed character failed to show any cause of death. (Vide Cases 18 and 19.)

In addition to these cases on which Rammstedt's operation was performed, we have selected two cases in which circumcision so completely relieved the obstructive symptoms that they are worthy of note. If we do not report in detail all cases where the results of circumcision might support our contention that phimosis is the most important cause of added spasm, it is only because we do not wish unduly to labour the point.

CASE 18.—A male child, with symptoms of projectile vomiting, constipation, and wasting. Phimosis of the usual type was marked. Visible peristalsis was noted, but no tumour was felt. Circumcision was followed by immediate cessation of vomiting and the passage of copious greasy stools. This amelioration of symptoms continued until sudden death occurred 60 hours later. Post-mortem examination showed no pyloric hypertrophy, and the cause of death is unexplained.

CASE 19.—This is of exceptional interest. A male infant, in whom visible peristalsis and a palpable tumour, added to the characteristic history, established the diagnosis. The usual type of phimosis indicated circumcision, which, with one relapse, gradually, but completely and permanently, relieved vomiting and constipation. Gain in weight commenced on the eighth day, and stools were becoming normal about the eleventh or twelfth day. On the thirteenth day, five loose, green, undigested stools were passed containing mucus. On the fourteenth day 7 oz. in weight were quickly lost, and the baby died quite suddenly.

In this case all the symptoms of pyloric obstruction were relieved by circumcision, and the definite improvement in the stools at about the eleventh or twelfth day (together with the preceding steady gain in weight) supports our experience—i.e., that pancreatic function begins to be re-established about this time after the relief of the pyloric obstruction. It is possible that this child, already weakened by starvation, could not withstand even the slight toxæmia which may have accompanied a mild infective diarrhoea. The stools were normal for the 24 hours preceding death.

#### *Details of Operation Performed.*

A study of these 17 cases teaches much in connexion with the actual performance of the operation, and as our experience has shown us that the success of the operation depends in no small measure on apparently insignificant details, the procedure, as we now practise it, should be described. The essence of the operation is its simplicity

FIG. 2.

and rapidity; and this, being the case, there is no necessity for hurry. It can be quietly and comfortably performed with care and deliberation in a minimum of five minutes and a maximum of seven minutes. If everything goes smoothly the latter figure need never be exceeded. A special knife has been made by Messrs. Allen and Hanburys in order to combine rapidity with safety. It is exceedingly simple and consists of semicircular cutting blade on one side with a blunt separator on the other, so designed that there are no sharp points in the cutting part which could inadvertently damage the gut. (Fig. 2.)

This knife is held like a pen, the cutting side being used first, and then the knife turned over and the blunt separator employed for completing the division. The abdomen is opened by an incision about 1½ in. long, about ½ in. below the costal margin, at about the junction of the outer and middle thirds of the right rectus. The incision is continued

through the rectus fascia and the muscle is split. The peritoneum is opened for about 1 in. in length and a pair of artery forceps clipped on it at either extremity. Such an incision usually exposes the liver in about the upper two-thirds of its length. The liver is gently rotated upwards and the stomach wall lifted out of the wound by picking it up with a pair of forceps. The stomach is caught with the finger and thumb of the right hand and lifted gently upwards and to the left. At this point there often may be experienced a little difficulty in presenting the pylorus in the wound. We have observed that any degree of traction influences (sometimes to a marked extent) the respirations, and so the child's general condition. In order, therefore, to avoid traction we find that the best manoeuvre is to hold the stomach wall near the pylorus out of the wound with the right hand, while with the left finger and thumb the abdominal wall is pressed back behind the pylorus rather than the pylorus brought up to the abdominal wall. There is much less disturbance to the respirations if this simple manoeuvre is remembered and practised. The left hand now holding the pylorus, the incision is made longitudinally with the cutting part of the knife in the whole length of the hypertrophied part, stopping just short of the normal bowel on the duodenal side, but carried well up into normal stomach wall. (In the white, large, avascular type the commencement of oozing is the indication that normal tissue is reached.)

The site of the incision deserves a word. This should be placed as far back as can be comfortably arranged, since it then falls into alignment with the plane of the lesser curvature. In the large avascular type this plane is easily recognised as an area short of which the termination of the circular vessels can be clearly seen, and therefore as the situation of choice for the incision. In the small vascular type this area can only be selected in a speculative way by placing the incision as nearly in a plane with the lesser curvature as possible; or, in other words, as far back as can be managed comfortably. The incision is deepened with the knife edge in the middle of the tumour until the pearly mucosa is seen, and when this is exposed, towards either extremity, just short of the termination of the hypertrophied area. The knife is now inverted and the remainder of the operation completed with the blunt separator. The division in the stomach side is carried by a cutting movement of the blunt separator until the mucosa is seen lying beneath the thin and normal stomach wall. Finally, when the mucosa has been exposed over the whole length of the original incision, the blunt separator, by a side-to-side movement, combined with a little pressure of the instrument and a little squeezing with the left finger and thumb grasping the pylorus, completely frees the mucosa from the muscular wall, and allows it to protrude a short distance into the severed outer coats. These manoeuvres take longer to describe than to practise. The pylorus and antrum are then returned to the abdomen and the abdominal wound sutured in layers. The whole operation can be performed quietly and comfortably in 5-7 minutes, and can always be guaranteed to last no longer than ten minutes. The simplicity and rapidity must appeal to every surgeon once it is recognised that such a wound in the gut can be left open with impunity. The most important point to remember is the adequate division of the sero-muscular coat on the stomach side; Case 5 illustrated the necessity for full division on the stomach side until normal stomach wall is reached. In confirmation of this may be quoted a case of Mr. L. E. Barrington-Ward's at Great Ormond-street. This child after operation had persistent vomiting, which was so characteristically of the obstructive type that Mr. Barrington-Ward operated a second time, completing the division of the hypertrophied portion on the stomach side. Vomiting ceased and the child recovered.

Mortality.

It will be evident that our first four cases gave high hopes of a safe operation with small risk. Subsequent experience was less fortunate so far as our figures were concerned, but very valuable for the purpose of establishing this operation as the method of choice in all cases. Our total mortality in all cases of Rammstedt's operation is 41.1 per cent., a marked improvement on the previous 100 per cent. Up to January, 1919, the total figure in hospital worked out at 38.8 per cent. In order, however, to ascertain the intrinsic value of this operation in uncomplicated cases, it is only fair that Cases 10

and 11 should be excluded, since they both died of purulent bronchitis after an operation performed (as offering, in our opinion, the only chance of recovery) during an attack of influenza and bronchitis then prevalent. This gives us 15 cases with 5 deaths, or a mortality of 33.3 per cent. Of the 4 remaining deaths, 2 (Cases 5 and 8) are attributable to lack of experience—i.e., to easily avoidable causes. For while Case 5 died from insufficient division, Case 8 died as the result of dividing too much. Any fair estimate of the intrinsic mortality of Rammstedt's operation, therefore, will be one which excludes deaths attributable to inexperience. Excluding these two cases, we have 13 cases with 3 deaths, or a mortality of 23 per cent. It will be seen that, with the operation conducted as we describe it (together with the indications for operation, palliative and post-operative treatment, which we shall shortly describe), the operative mortality of all uncomplicated cases (however poor their condition) works out at 23 per cent. We have only had two unexplained deaths in children operated on in good condition, for the other two remaining fatalities (Cases 7 and 17) were both very minute, sickly, and marantic infants. Therefore, while we estimate the mortality in all uncomplicated cases at 23 per cent., we feel justified in saying that mortality in favourable or early cases is represented in our series by 11 cases and 1 death, or a mortality of 9 per cent. A mortality of 9 per cent. in hospital practice, even with all unfavourable cases excluded, represents a striking plea for the adoption of this operation. Finally, we wish to lay stress on the fact that whereas the recovery of our first four cases was surely due in a large measure to good fortune, the lessons of our subsequent failures have, so far as in us lay, been turned to good account. Thus our results are improving steadily, as evidenced, not only by the recovery of seven out of the last eight consecutive cases, but by the rarity of post-operative vomiting in the later cases. We feel we can confidently predict a marked improvement in the figures in the near future.

Post-operative Temperature.

There is one point in connexion with this operation which is of great interest—namely, the post-operative temperature. We append a typical chart in one of our series where the child made an uninterrupted recovery. (Chart 4.) It will

CHART 4.

be seen that the temperature rose on the evening of operation to 105.2°, an ice-bag being applied to the head whenever the temperature rose above 104°. Finally, two of our series (Cases 12 and 17) died somewhat suddenly and unexpectedly (when their excellent progress had placed them out of obvious danger) three and four days respectively after operation. Progress had been eminently satisfactory and unaccompanied by vomiting. Post-mortem examination showed no obvious cause of death; and our view that these deaths

were independent of the operation is supported by a case (Case 18) of pyloric spasm where circumcision alone produced complete relief of symptoms. 60 hours later the baby died suddenly. Post mortem no cause of death could be found, and no hypertrophy of the pylorus was present. Case 19 is another similar instance in a case of hypertrophy, where circumcision relieved the obstruction. A study of nine cases which recovered shows that the highest temperatures reached were respectively 105°, 104°, 105°, 101·4, 105°, 104°, 103·4°, 105°, and 104°. Thus in only two instances did the chart fail to register 104° at least. The curious fact in this connexion is that the babies did not seem ill; and in several instances the observer would not have realised such an abnormal temperature from the child's appearance. The patients seemed to be none the worse, and the temperatures always fell to near normal on the second to the fourth day. We have been unable to find any satisfactory explanation of this phenomenon. It is not due to any infection at the site of the pyloric incision, for the post-mortem examinations never showed signs of peritonitis, with the exception of Case 8. Three of the cases showed a variable temperature previous to operation (from 97° to 101° or 102°), but this may have been influenced by saline and glucose infusion, and will not help to explain the abnormally high temperature after operation in practically all cases. The rise of temperature is of no importance, and we think it is probably central in origin. The application of an ice-bag to the head quickly reduces the hyperpyrexia. The other feature shown in this series is that vomiting only occurs exceptionally (and is not projectile in character) if the operation has been properly performed.

#### *Advantages of Rammstedt's Operation.*

From our study, up to the present, therefore, we do not hesitate to advocate Rammstedt's operation when surgical interference is necessary; and, in our opinion, it will in the near future take the place of every other surgical method devised for the cure of hypertrophic stenosis of the pylorus. In further support of this, Rachford also reports a post-mortem examination, six months after Rammstedt's operation, where the child had died from other causes. In this case, contrary to his experience after gastro-enterostomy (vide supra), no trace of the tumour could be found. Our own experience, both clinical and post mortem, has shown that after Rammstedt's operation the pyloric hypertrophy rapidly disappears. For in Case 17 five days after operation the hypertrophy had diminished by at least two-thirds of its former extent, and the mucous membrane lay almost smoothly round the incision. Further, so clearly and smoothly had the incision been sealed over by organised lymph, that it was difficult to reopen the wound in the sero-muscular coat.

#### IV.—Treatment.

It is a regrettable fact that the net results of treatment by all methods in all cases have not been good. During the years 1915-16-17 54 cases were admitted to Great Ormond-street. The majority of these were treated without operation, and in those where operation was performed various methods other than the Rammstedt's were employed. The total mortality was 80·5 per cent. The mortality of those operated upon was 100 per cent. There are three explanations of this fact:—

(a) The lack of an ideal operative technique where operation was indicated.

(b) The insufficient appreciation of any reasoned indications for operations owing to

(c) Failure to realise the true mechanism of the pyloric obstruction.

(a) A detailed analysis of the various operative procedures has been given, and it has been shown that Rammstedt's operation, by virtue of its simplicity and applicability to all cases (both early and late), is the only one to be advocated when palliative treatment has definitely failed and surgical intervention is indicated. Thus, at Great Ormond-street during the past year, when this operation was first performed, the mortality of our cases operated upon was 41·1 per cent. while the total mortality showed a proportionate decrease.

(b) and (c) Until the present no rational explanation has been offered of the nature of the pyloric obstruction. Thus, failing a sound basis for treatment, such treatment has been

largely empirical, or dependent only on individual judgment. In a previous communication on the pathogenesis of pyloric stenosis an explanation has been offered of the occurrence at birth of varying degrees of pyloric hypertrophy. It was shown that in the large majority of these cases certain subsidiary conditions added to the stenosis produced by antenatal hypertrophy, and initiated the symptoms of obstruction. These are:—

(1) Inhibition of pancreatic secretion dependent upon the original hypertrophy, or upon the superadded conditions of (2) gastritis, (3) spasm due to phimosis, (4) spasm from unknown causes.

(1) The normal sequence of events in which the amount of pancreatic secretion varies directly with the amount of acid chyme passing through the pylorus and over the duodenal mucosa has been shown by experimental physiologists. It has also been shown that, until such time as acid chyme has been neutralised by alkaline pancreatic secretion, the pylorus remains closed. We believe that the pancreatic function, antagonised originally by hyper-adrenalism, is at least diminished, so that the balance between these two fluids is disturbed. This results in a prolongation of the time during which the duodenal contents remain acid, and thus during which the pylorus remains closed. The function of the gland never can have been entirely abolished, but the formation of its external secretion would have to be stimulated indirectly by acid chyme in the duodenum. It follows that a diminishing amount of acid chyme passing through the pylorus results in the exhibition of still less alkaline secretion, and there is the increasing tendency of the pylorus to remain closed. So the vicious circle is established.

It must be conceded then that, when the amount of pyloric hypertrophy existing at birth is sufficient in itself to cause obstruction, the amount of pancreatic secretion exhibited will be the minimum. In this instance the vicious circle is established at once. Again, when there is a moderate degree of congenital hypertrophy the vicious circle will take longer to become established unless some other added cause results in a more rapid closure of the orifice. And, again, where there is only a slight degree of congenital hypertrophy there may be sufficient acid chyme passing through the pylorus to satisfy physiological requirements. In this instance the child would never show symptoms of obstruction unless there were added some other cause of spasm severe enough to complete the closure. And, finally, we must draw attention to those cases where there was no ante-natal hyper-adrenalism, and therefore no congenital hypertrophy, but where obstruction may result from severe pylorospasm alone. In this instance the obstruction is completely relieved by the removal of the cause of the spasm.

Such cases should never be considered in the same category with congenital hypertrophic pyloric stenosis.

(2) *Gastritis*.—Food remaining in the stomach an undue length of time will set up a retention gastritis, with consequent swelling and hyperæmia of the gastric mucosa. This clearly contributes towards the closure of an already stenosed pyloric orifice. The urgency of the symptoms will depend upon the relation between the degree of hypertrophy and the amount of gastritis.

(3) *Phimosis*.—It has already been shown how phimosis, or preputial adhesions, may produce spasm of the pylorus. We believe this to be the most potent cause of added spasm. This explains the fact that the great majority of babies presented for treatment on account of pyloric obstruction are boys.

It will be shown that these statements as to the relation of phimosis and gastritis with pyloric hypertrophy are amply borne out by the results of treatment.

(4) *Spasm from unknown causes*.—It cannot be claimed that gastritis and phimosis are the only causes contributing towards the complete closure of the pyloric orifice. John Thomson reports cases that have been cured by the administration of sedatives such as chloral hydrate; and we realise that there may be many unrecognised causes of pylorospasm, which, according to the relation between their severity and the amount of hypertrophy, might contribute towards closure of the outlet.

It will now be seen that, apart from extreme congenital hypertrophy, we are in a position to gauge the urgency of the

obstruction by the degree of secretory inhibition. This cannot be estimated accurately, but there are certain indications upon which conclusions may be based. Thus, when insufficient food for physiological requirements passes the pylorus, there are, in addition to the signs and symptoms upon which the original diagnosis rested, loss of weight and infrequent, hard, dry bowel motions. The consistence of the motion depends upon the absence of secretion, its size on the amount of food passing the pylorus. Soon after the obstruction is relieved, in addition to the cessation of vomiting and gastric peristalsis, the stools become more bulky, loose, greasy, and more frequent. The motious are of this character because, although the gastric secretion has a slight lipolytic action, pancreatic secretion is inhibited, and most of the fats are coming through incompletely changed. A reference to all our cases in which symptoms of obstruction were relieved with or without operation will support this statement. The digestion of the proteids we can accomplish, in a measure, by peptonising the milk, but the fats we cannot sufficiently modify. Emulsification and saponification cannot proceed in the absence of pancreatic secretion. As soon as this function has been re-established the stools will resume their normal consistence and the child will gain more rapidly in weight. It is against reason that the function of the pancreas, which has been inhibited for varying lengths of time, should be resumed the moment the obstruction is relieved. Accordingly we have found that the length of time necessary for the pancreatic secretion to be re-established is almost directly proportionate to the length of time it was in abeyance. Thus, children whose pyloric obstruction had been relieved by operative or palliative treatment ceased to vomit and began to gain in weight in from 10-14 days from the beginning of treatment. The stools in some still showed incompletely changed fat, and in them improvement, as evidenced by gain in weight, was not marked until the stools became normal. A reference to the charts of our cases will bear this out.

The only exception to this is in the case of girls. In them the onset of symptoms was more gradual, and the improvement consequently much slower. Reference in this connexion should be made to Cases 14 and 15. This, again, supports our contention that phimosis is the most potent cause of added spasm. Girls being exempt from this influence are much slower developing complete closure. In consequence of this the pancreatic gland, functioning incompletely for a long time, will take a proportionately long time in regaining its function. It is only after due appreciation of all the factors contributing to pyloric obstruction that we may now consider ourselves in a position to place the treatment on a rational basis. There are very definite indications as to the line of treatment to be advocated: (1) It must be *radical* when the secretory inhibition is established at once by a maximum amount of congenital hypertrophy at birth, and a minimum effect from added causes. (2) It will be *palliative* until we have determined, by treatment of the added causes of closure, whether their influence was the preponderating one or not. (3) We have a critical point in the progress of the treatment at which we know whether the obstruction has been relieved by the removal of one or more of these added causes. There are three general considerations in the treatment, common to all.

1. *Diet*.—In all cases the food given should be peptonised milk. This is not the place to establish the value of milk as the best artificial food, and we shall not labour the point. Breast-fed babies admitted to the hospital are given as many feeds from the breast as practicable and complementary feeds of peptonised milk. From the preceding observations it naturally follows that the milk should be peptonised. With one of the various media for pancreatisation we have the means of compensating for (at least as far as the proteids are concerned) the deprivation of pancreatic secretion. There is a 25 per cent. dilution of the milk in the process of peptonisation, and it is clearly superfluous to dilute further a milk whose proteid is already prepared for absorption. The fats and carbohydrates are well below 3 per cent. and require no further dilution. Although we know that fats are not well tolerated, it is not wise to eliminate them entirely, since their very presence in the duodenum may help to provoke the exhibition of lipolysins. We have not found it necessary to modify the quantity or the feeding interval. The usual amount for the weight and age of the child should be given, with no more than nine feedings in the 24 hours.

2. *Gastric lavage*.—In all cases gastric lavage should be employed. This treatment is based on the knowledge of the importance of gastritis as a contributory factor to completing pyloric obstruction. A mildly alkaline solution is used through a nasal or oesophageal tube. It should be carried out once or twice a day, depending upon the severity of the local symptoms. After operation it may be discontinued, since the obstruction has been relieved, and the re-establishment of normal drainage is all-sufficient. Otherwise, it is continued until the wash-out is free from mucus. Lavage is never stopped abruptly, but the intervals between the treatments are gradually lengthened until they can be dispensed with altogether.

3. *Constipation*.—Recognising the cause of constipation to be lack of bulk as well as of secretion due to pyloric obstruction, no cathartic should ever be given. A small oil enema or rectal lavage is all that is necessary. Apart from general considerations, the treatment will naturally fall into divisions: (1) Urgent treatment, (2) palliative treatment, (3) radical treatment.

(1) *Urgent treatment*.—Although we have demonstrated above that there is a critical point up to which we may safely pursue palliative treatment, there are two groups of cases which must be considered as presenting urgent indications for radical treatment.

(a) *Extreme congenital hypertrophy*.—In this small group the amount of hypertrophy present at birth is sufficient to cause obstruction. The babies forcibly eject the first and every subsequent feed, and gastric lavage with (in boys) circumcision fails to relieve the symptoms, even temporarily. These cases are to be considered as surgical emergencies, and should be operated upon as soon as the diagnosis is established.

(b) *Frail, puny babies*.—Some babies are not presented for treatment until the wasting, consequent upon the obstruction, is extreme. They have practically no reserve strength to face a possible operation. If their history is that of group (a) they are treated in the same way. If the symptoms date from later in life some factor has contributed to the closure of the pylorus. They are treated in the routine way with gastric lavage and fed with peptonised milk. Their strength is further fortified by the subcutaneous injection of 2 per cent. glucose in saline solution. In boys, if phimosis or preputial adhesions exist, circumcision is performed. Unless there is immediate (within two or three days) cessation of vomiting and the evacuation of larger, greasy stools operation takes place at once. If improvement is not obtained it may mean that the effect of hypertrophy preponderates over that of any added cause. These babies are so frail that we cannot afford to wait for the critical point—i.e., 10-12 days from the commencement of treatment. These, too, are to be regarded as surgical emergencies and operated upon immediately. In this connexion reference should be made to Case 17. It is thus seen that urgent treatment means operation upon certain cases within the tenth to twelfth day limit.

(2) *Palliative treatment*.—(a) *Secretory inhibition*.—It has been shown that the ultimate effect of stenosis of the pyloric outlet is suppression of the pancreatic secretion, which very suppression in itself contributes to the closure of the orifice. This condition can only be treated in one way. There must be sufficient acid chyme in the duodenum to stimulate the pancreas to normal activity. This can only be accomplished by relieving the pyloric obstruction. Thus, if by 10-12 days the routine treatment of eliminating any other cause of added spasm has not succeeded in securing a cessation of vomiting and the appearance of the characteristic stools, operation is indicated. We may say here, and this will also apply to any similar circumstance, we do not demand an *absolute* cessation of vomiting. There may be an occasional non-projectile vomit, but this is of no moment if the stools show that a fair amount of food is passing the pylorus and there is ever so slight a gain in weight. Our observations have taught us that all babies, in whom every contributory cause of closure has been eliminated and in whom symptoms of obstruction persist, come to operation. It has been shown that in no other way can the pancreas be stimulated to renewed function. Reference in this connexion should be made to Cases 16 and 17.

(b) *Gastritis*.—It is probable that in most cases of pyloric obstruction a certain amount of retention gastritis with

consequent swelling and hyperæmia of the mucosa is present. Where this is sufficient to complete the closure of the pyloric orifice its relief should result in the removal of the obstruction. Thus, in the case of a male infant recently admitted under Dr. Still the diagnosis was established in the usual way. There were neither phimosis nor preputial adhesions, therefore circumcision was not performed. He was fed on peptonised milk, and his stomach was washed out daily. About the twelfth day, the vomiting, which had been variable, ceased altogether; the stools, which had been occasionally loose, became more bulky, greasy, and more frequent, and he began to gain in weight. His improvement has been progressive ever since. In the case of Ivy M., the same procedure was followed, with similar results. Thus, gastritis in itself may be the determining factor in producing closure of the pylorus. If successful results are not obtained by this routine, and the possible effects of phimosis in boys have been eliminated, only one cause of obstruction remains—the preponderant element of hypertrophy with its attendant secretory suppression, for which operation is the only remedy.

We have referred elsewhere to the fact that girls do not behave in quite the same manner as boys. Uninfluenced by phimosis, the most potent cause of added spasm, they are slower developing symptoms of obstruction, and they will be correspondingly slower in showing improvement following relief from obstruction. For this reason we are disposed to wait longer than the 10–12 days before deciding that operation is indicated upon girls. We advocate this because the pancreas may be slower in regaining its function. Thus, if at the end of 10–12 days from the commencement of treatment there is still an occasional vomit with constipated motions, we do not operate unless there is marked or progressive loss in weight. We wait until a period of time has elapsed corresponding with that during which the symptoms of obstruction were developed.

(c) *Phimosis*.—We shall not again enter into a discussion of the relation of phimosis to pyloric stenosis. It is sufficient to repeat that we consider it the most potent cause of added spasm in boys. If babies in whom the diagnosis of congenital hypertrophic pyloric stenosis has been established show phimosis or preputial adhesions they should be circumcised, or the adherent prepuce separated at once. In Case 16 circumcision was immediately followed by complete cessation of vomiting, and the appearance of characteristic motions. Within a few days, however, the symptoms of obstruction began to reappear, and were well established by the tenth day. In this case phimosis was only a contributory cause of spasm, and was not the only one. Gastritis was eliminated by the failure of lavage to relieve the symptoms, since these reappeared. There remained the only cause of obstruction—hypertrophy plus secretory inhibition, for which operation was performed and gave relief. And in support we may again call attention to the fact that the child showed the largest pylorus we have ever seen.

Again, in Case 19, under Dr. Colman, circumcision was performed. There followed occasional vomits and loose motions. After the tenth day the patient did not vomit again. On the eleventh and twelfth days there were the frequent, bulky, greasy motions, and he began to gain. His improvement was progressive up to the time when sudden death occurred, as already reported.

There is also a child under the care of Dr. Colman who is now under similar treatment, and appears to be following a most satisfactory course. In these cases phimosis itself was the predominant factor in completing closure of the stenosed pylorus. On the other hand, Case 17, admitted under Dr. Poynton, was circumcised without any subsequent relief from the symptoms. As it came under Group I. operation was performed at once with immediate relief from the symptoms. In this instance phimosis had nothing to do with the closure of the pylorus.

(d) *Unknown causes of spasm*.—We must admit that there may be a very small group of cases where some unrecognised cause of spasm determines the closure of the stenosed pyloric orifice. We cannot satisfy ourselves that we have found any in our experience. But such good observers as John Thomson have had success, in some cases, by the administration of sedatives such as chloral hydrate. Such cases must be very few in number, and only the results of treatment such as we are advocating could differentiate them.

(3) *Radical treatment*.—The treatment becomes radical—that is, the pylorus is operated upon—when palliative treatment definitely fails to relieve the symptoms of obstruction by the twelfth day. This failure would mean that all causes of obstruction, other than the hypertrophy itself, had been removed; the only relief now is operation. During the twelfth day interval the symptoms may fluctuate. The vomiting may be non-projectile and less frequent. Gastric peristalsis is seen only occasionally. The stools are sometimes constipated and sometimes loose. The weight will vary between small gains and losses. The subcutaneous injections of saline and glucose will prevent any marked wasting. These fluctuations are of no moment before the twelfth day, but after this point they would indicate the inability of the pylorus to relax permanently. We do not say that all babies left longer than 12 days will not recover, but we do think that there is sufficient evidence to show that if they are to recover under palliative treatment they should usually indicate definite evidence of doing so by the end of the twelfth day. (We make an exception, as mentioned above, in the case of girls.) We consider that, after this point, the risk from operation is much less than the risk from a more or less permanent inhibition of pancreatic function becoming established, owing to prolonged pyloric obstruction. If this happened, even operation would be of no avail, and the children would die from marasmus. Moreover, a relapse might occur when operation would have to be performed under far less advantageous circumstances. (Vide Case 7.) The treatment, then, of babies in whom symptoms of obstruction persist beyond the twelfth day is surgical, and Rammstedt's operation should be performed.

With regard to the prevention of sudden deaths from unexplained causes, it is very difficult to suggest any way in which this definite percentage of losses, with or without operation, can be obviated. Similar accidents are reported in America and are well recognised. We have not yet made trial of blood transfusion previous to or after operation, but we propose trying a series of cases in this way, and comparing the results obtained with the figures we have already given.

#### V.—*Post-operative Treatment*.

When the child is returned to bed from the operating theatre it should be kept warm with wool wrapped about the extremities and preferably nursed on a water bed. If there is no shock we prefer the semi-upright position. There is sometimes a mild degree of post-operative bronchitis, which can be treated better in this position.

*Diet*.—This is an important detail. We have shown that the period of time necessary for the pancreas to regain its function is from 10 to 12 days. During this time peptonised milk should be given. Our practice is to give one ounce four hours after the operation, and a similar amount every four hours for the first 24 hours. The second 24 hours an ounce and a half is given every three hours. After this an amount is given according to the weight and age of the child. We have never found it necessary to feed smaller quantities. When the stools cease to show incompletely changed fats (usually about the tenth to twelfth day) the food is changed to citrated modified milk. This change in the stools would indicate a return to the normal outflow of pancreatic secretion. Beyond this point they are fed as normal babies. We make an exception to the 10 to 12-day limit for this change of food in the case of girls. As shown before, in them the pancreas is slow to regain its secretory function for reasons already indicated, and therefore the peptonised milk usually will have to be continued longer than 12 days. Case 15 illustrated this. At the twelfth day the stools were still rather loose and greasy, and she was gaining very slowly. Citrated modified milk was given. The stools became more undigested and she began to lose weight. The food was again changed to peptonised milk and she immediately began to gain. The stools were still loose, but were free from curds. She is still on peptonised milk, which will be discontinued as soon as there is no evidence of undigested fat in the stools.

During the first few days after operation, while the child is taking insufficient food, we continue the saline and glucose infusions. At first eight ounces a day, and later four a day, may be given. The infusion should never be repeated unless the one previously given has been completely absorbed. If absorption is unduly slow it may be

expedited by the hypodermic injection of a  $\frac{1}{2}$  c.cm. of pituitrin. The combined saline-glucose infusion with pituitrin treatment is doubly useful, in that it combats post-operative shock, and replaces, in a measure, the food which must at first be withheld. We have said nothing about medicinal treatment, and we think there is seldom any indication for the administration of drugs. The only fear after operation is shock, and this is best treated in the manner described. Brandy might be advocated, but our experience has taught us that it may cause vomiting. As most of these small patients are in a precarious condition, they are not able to withstand the extra demand on their reserve made by vomiting. The work recently done on direct blood transfusion has suggested to us its employment on the more feeble of these patients. In a further series of cases it is intended to practise this at the time of operation. In cases which do not come to operation, we think this might advantageously be employed about the end of the second week, since two or three children have died from unexplained causes about this time, although the symptoms of obstruction had been relieved.

#### SUMMARY OF CONCLUSIONS ON BOTH CONTRIBUTIONS.

1. Congenital pyloric hypertrophy is the result of prolonged ante-natal spasm induced by hyper-adrenalism.

2. Pyloric obstruction is completed by two secondary influences: (a) retention gastritis with consequent swelling of the mucosa; (b) added spasm due to several causes; foremost by *phimosis*.

3. The final results in the closure of the pyloric orifice are: (a) absence of acid chyme in the first part of the duodenum, leading to (b) failure of secretin formation, leading to (c) suppression of pancreatic secretion. These factors themselves further induce (d) inhibition of the normal pyloric relaxation and establishment of the "vicious circle."

4. Positive diagnosis should never be made without the demonstration of a palpable tumour.

5. Rammstedt's operation is the operation of choice.

6. Fulminating cases demand immediate operation.

7. In all other cases palliative treatment should first be adopted as follows:—(1) Feeds: peptonised milk in appropriate quantities; (2) gastric lavage; (3) circumcision; (4) subcutaneous infusion of saline and 2 per cent. glucose when necessary; and possibly (5) administration of chloral hydrate.

8. *Duration of palliative treatment*: (a) Very wasted and weakly infants. If there is no relief of symptoms in 48 hours operation should be performed without delay. (b) In the majority of cases palliative treatment is to be persevered with for from 10 to 12 days.

9. The critical time at which failure or success of palliative treatment can be gauged is from 10 to 12 days from the commencement of treatment, and coincides with the re-establishment of pancreatic function in successful cases.

10. Failure to improve after this point constitutes an indication for operation in boys, but not necessarily in girls.

11. Sex incidence is about equal; *phimosis* being the determining factor in the onset and severity of symptoms in a large proportion of male subjects of pyloric hypertrophy.

12. Post-operative diet should consist of peptonised milk until pancreatic functions have been re-established.

Finally, we cannot conclude this study without expressing our thanks to the staff of the Great Ormond-street Hospital for their courtesy in placing at our disposal their cases and the hospital notes.

## FURTHER EXPERIENCES IN COLONY TREATMENT AND AFTER-CARE.

BY SIR G. SIMS WOODHEAD, K.B.E., V.D., M.A.,  
M.D., LL.D.,

FELLOW OF TRINITY HALL, AND PROFESSOR OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE;

AND

P. C. VARRIER-JONES, M.A. CAMB., M.R.C.S.,  
L.R.C.P. LOND.,

FOUNDATION SCHOLAR, ST. JOHN'S COLLEGE, CAMBRIDGE; HONORARY MEDICAL OFFICER, CAMBRIDGESHIRE TUBERCULOSIS COLONY; AND TUBERCULOSIS OFFICER FOR THE COUNTY OF CAMBRIDGE.

### III.<sup>1</sup>

THE incidence of the new problem involved in the treatment of the discharged tuberculous soldier and sailor has so shaken our old beliefs and jarred our prejudices that we are in danger of attempting to grasp at an idea which we imagine may help us in the solution, while failing to evaluate the idea in that its fundamental principles are not understood. From the number of inquiries received, and from conversations with many, both lay and medical, who have visited Papworth Colony—interested in the problem of the treatment of tuberculosis—it has been brought home to us that even amongst those who have given, or are giving, attention to the matter there is a welter of opinion which must be rescued from chaos and carefully arranged and classified before any concerted action can be taken.

#### *Chances of Success in Change of Employment.*

The simple and oft-repeated formula, "Seek a job in the open air," glibly offered to the middle-aged mechanic, and the equally casual advice "to take things easy for the next three months or so" given to a man with a wife and six children to support, indicate only too clearly that little mental effort can have been brought to bear on the actualities of the situation. If there is one thing that experience of colony work has made clear it is that, as a rule, it is futile, and will now be criminal to give the above advice, unless it is realised that if there is one form of occupation more unsuitable than any other for the consumptive it is a job as an unskilled farm labourer.

The job in the open air—the utopian dream of the unthinking adviser—may be either Scylla, Charybdis, or both, but usually threatening the consumptive with destruction. The idyllic summer holiday at a farm, with its peace and rest, its plain but nourishing milk and eggs, its new and temporary interests, and its gentle exercises in the open air, is very different from the strenuous and exacting life of a farm labourer, even at an enhanced wage of 40s. per week. The unskilled hand, the untrained eye, and the inexperienced brain are of little value to the farmer, and certainly cannot be profitably employed. Though many members of the medical profession, and the vast army of voluntary workers, who so frequently give this advice do not realise its futility, it is a matter to which the consumptive is fully alive. It is only necessary to talk to these men and to obtain their confidence to have it brought home to one that they know better than their advisers that to set an unskilled man to work at any skilled trade is not only economically unsound, but physically detrimental and morally and socially delusive. To bring the matter home to ourselves we have merely to imagine how sorry would be the plight in which most of us would find ourselves were it necessary for us to give up our profession and seek pastures new. Why, then, give advice—fortunately rarely followed, or if followed quickly given up—which nine times out of ten can only be a source of disappointment to all concerned? The question:—How many men can be trained in agriculture in the course of six months? can only be put by a town-bred man with no knowledge of country life, and as it is impossible in six months to train a healthy man to follow a complicated industry such as agriculture, how much less is this possible in the case of a 50 per cent. man suffering from tuberculosis. Had the colony committee the changing of a man's occupation from that of an artisan or clerk to that of a farm labourer, or even a small-holder, for its objective it must

<sup>1</sup> Part I. was published in THE LANCET of Nov. 24th, 1917, and Part II. in THE LANCET of August 3rd, 1918.

CHILD WELFARE IN BRITISH GUIANA.—The Baby Saving League of British Guiana was started five years ago. We have now received the (fifth) annual report for the year 1918. Such an institution appears to be greatly needed, for the infant mortality-rate is extremely high. For the year 1918, for the whole colony, it was 223 per 1000; for the Portuguese, 157; for the East Indian race, 241; for the Chinese, 143; and for the black races, 225. The need for a larger population in British Guiana is an urgent one. It is pointed out in the report that East Indian immigration is likely to be abolished, and a larger supply of labour is needed in order to develop the resources of the interior and to maintain the industries which are already established on the coast. Shortage of the labour supply is already reflected in the diminished acreage under sugar, notwithstanding the enhanced prices due to the world-war.;

inevitably court failure. A genuine case of pulmonary tuberculosis with a definite and progressive lung lesion will undoubtedly benefit by a prolonged stay under ideal colony conditions, but very few will ever be able to stand alone, and, working from morning till night, live on the produce of a small holding. The arrested condition of the disease in these cases is so unstable that the proposition cannot be a paying one, and this instability is the main medical cause, not taking into consideration economical and psychological factors of failure, and must necessarily remain so until some method of stabilising the arrest is attained. One of the difficulties met with in dealing with such a vast problem as that of tuberculosis is that exceptional results which do not appear to bear out general experience crop up now and again; but as a rule, if these exceptional results are carefully analysed, it will be found that the principles on which the colony treatment is based are sound and have not been violated, and that other special factors have come into play and have altered the course of events. In some cases change of employment has undoubtedly been attended with success, but these successes are few and far between, and have, as a rule, been associated with a group of such favourable contributory conditions that the truth of the general proposition is in no way countered. For example, a sympathetic employer may be an important factor in the determination of an apparently exceptional success fundamentally altering the patient's whole economic condition. He permits, nay ensures, the working of shorter hours, later morning rising, more prolonged noonday rest, with ample time for meals, and one of the prime factors in success—the feeling of the absence of competition is assured. The feeling “I shall not get the sack even if I slack a little when I feel weary” affords great psychological comfort. It must be remembered, however, that such philanthropy does not flourish freely in the largest concerns and in the limited liability companies; but the colony having learned much from the sympathetic employer, takes his place, and must strive to provide for all cases of tuberculosis not only the above conditions, but in addition suitable dwellings, good food, and protection from the economic struggle—the salvation of the consumptive working man. The exceptions proving the rule therefore, instead of militating against the general proposition, are of the greatest service as indicating the proper method of tackling the general problem. It is not so much the change of occupation that ensures the favourable reaction, nor certainly is it the mere fact that the patient becomes a farm labourer; for there is no magic in that occupation. Nor, again, is a light open-air job a panacea for the disease. Patients working at either, or both, unless carefully watched and guided become steadily worse and inevitably head for disaster. We must realise the actual economic conditions that are assured when a sympathetic employer has the case in hand, and also that these are necessary for the success of the undertaking. These fundamentals, these economic conditions assured, we are afraid to disturb them in any way, and the problem seems to us so vast that we are almost afraid to do or say anything that might lead to such disturbance.

#### *Reason for Labour's Lack of Sympathy.*

Has it ever struck us how extraordinarily unsympathetic the mass of labour—“the labour world”—is toward all schemes of sanatoriums and the like, and, if so, has it ever occurred to us to seek the reason for this? It is obviously the same reason that underlies the apathetic attitude of labour to the Government's training schemes for disabled sailors and soldiers, which are little more than camouflage, the mere tinkering with a huge problem. What should we, as medical men, say if, owing to a shortage of doctors, it was seriously proposed to give men a six months, or even a 12 months intensive course in medicine and surgery in the large hospitals and then turn the recruits loose to practise medicine and surgery on the community? It may be argued that this is not an exact parallel, but it is sufficiently exact if we leave out of account the question of danger to the public and consider only the amount of knowledge which the man could acquire from such a course. For the training of an efficient workman the present course as recommended and provided is absurd, and the working man knows it. That the skilled artisan does not wish his trade to be exploited by an untrained person is another aspect of the question, but one of equal importance. If we are simply patching up a patient in order that he may return to his original surroundings, where he may infect other working men, small wonder

that the plan of utilising the sympathetic employer receives but scant consideration from the working man, who is thus called upon to run the risk not only of infection but also of diminished earnings due to the business being burdened by the introduction of the invalid.

The insufficiency of the training that can be given to a man disabled, whether by the loss of a limb or a lung, is very fully appreciated by the intelligent working man; not so fully by those called upon to advise, treat, and train him. The medical profession does not fully appreciate that there can be no other criterion of a patient's “cure” or of the arrest of his disease than that of earning capacity, more or less permanent. It is obviously of vital importance that the earning capacity of a consumptive should be restored to as nearly a normal level as possible. To alter a man's occupation, when the earning capacity of such a man is the standard of success, is no easy matter. Here earnings are of prime importance and a moment's thought will make it clear that in the majority of cases of pulmonary tuberculosis, those with well-developed disease, it is impossible for the earning power of the consumptive to be more than 50 per cent. of his normal—for him to be more than a 50 per cent. man. That some become 75 per cent. men is an encouraging fact, but we recognise that it is only under very special conditions that such a percentage is obtained.

#### *Consumptive's Hopeless Handicap in the Open Labour Market.*

If it be accepted that a “middle case” of consumption is unable to work for more than six hours per day at a trade which is not too laborious and not too technical, and is paid at a full trade-union rate of wages for those six hours, it is obvious that the man cannot earn during those restricted hours of work a sufficient sum to keep himself and his family in decent circumstances. In the ordinary workaday world an employer cannot be expected to take into his shops or factory a consumptive with a working capacity of only 50 per cent. and pay him above the trade-union rate of wages. There would soon be a general upheaval in that factory or shop, and a state of unrest such as that we have witnessed arising out of the exorbitant rate of wages paid to munition workers. Our hypothetical employer would have to be a philanthropist indeed who could or would consent, or dare, to adopt such a course. It is obvious, therefore, that even if we could find a sufficient number of sympathetic employers who would guarantee a full wage for a 50 per cent. worker our difficulties would not be at an end. A further subsidy is required, a subsidy that must come from the Government or State, as it is impossible to throw such a burden on the industrial employer of labour. As a rule, an employer asked to employ a consumptive answers that he would prefer to give a donation or subscription to some charitable institution, hospital, or sanatorium and have done with the matter. The disorganisation of business which would arise out of the employment of a consumptive on the only adequate basis, that of the maintenance of health of a patient and his family, is sufficient to undermine the whole scheme. Occasionally an employer willing to run the risk may be and is found, but the arrangement entered into does not as a rule last long. The danger of infection from the presence of a tuberculous worker is hinted at and rapidly passes through the shop. Moreover, if concessions as to hours, &c., are made to an apparently healthy man (the wound in the lung is not visible) it is with difficulty that the other workers are prevented from expecting and demanding similar concessions. The difficulties and obstructions set up by the trade-unions are equally great, in many cases debarring the consumptive from finding suitable employment. The embargo of the union is decisive unless the patient is a skilled workman, who in many trades must have served his full apprenticeship. This indeed is the fatal bar to the training of a consumptive in any new skilled trade. A few months spent in specially fitted-up shops at a colony is quite inadequate to obtain his admission into any skilled trade, in which wages are high, and, for the most part, adequate, and the corresponding trade-union, even should he have the ability to perform the work at the end of such a short period of training. From all points of view, then, the difficulty of training a consumptive in a new trade, to be carried on in the open market, is enormous, and there remain but the inadequately paid casual occupations, where the work is heavy and the remuneration poor, both factors to be avoided if success is to be attained or expected.

*Return of the Consumptive to His Own Trade.*

The myth of a "light job in the country" is exploded. The training of a consumptive in a "light remunerative calling" is not practical politics. There remain but two alternatives: (1) the consumptive must return to his own trade, or (2) he must become a permanent colonist. The former is the one usually adopted for the consumptive; it is at present the only course open to him, though in the majority of cases it must end in disaster. The economic conditions of competitive labour are against the man, and are fatal to success. The philanthropic employers who are willing to eliminate these fatal competitive conditions are few and far between, but to their sympathy and action we owe the cases which appear to provide exceptions to the rule; apparent exceptions only, but they serve as examples of methods which, if followed on a large scale, spell general success.

The nature of this method, call it after-care or any name which may indicate its nature, has as yet been but inadequately appreciated. The problem has almost invariably been viewed from the "individual cure" point of view, one small factor after another being taken and insisted upon. The new idea, which is the outcome of the colony as advocated at Papworth, is admirably expressed by Dr. H. A. Pattison in his study, "The Agricultural and Industrial Community for Arrested Cases of Tuberculosis and their Families," published by the Federal Board for Vocational Education, Washington, 1919. "Industrial communities," he says, "have developed rapidly in the country. Many of them have grown about a single industry for the sake of that industry, such as a steel mill, coal or mineral mine, &c. The converse proposition is the one I wish to offer, the development of industries around a community for the sake of that community." The same idea has been expressed as follows: "Let communities be started in which our consumptive soldier can live in his own home, shielded from the fierce competition of the outside world, a self-respecting worker, an economic asset. Let employment be found, the model factory erected, the hours of toil properly regulated, a fair wage paid."<sup>2</sup>

In other words, the rôle of the colony is that of the philanthropic but unfettered employer, with his factory open for the admission of those who cannot find work elsewhere, and where the mode of life—if a serious relapse is to be avoided—must be carefully regulated. That the disease will progress there can be little doubt, but the rate of its advance may be so controlled that the patient may yet enjoy many years of useful work and pleasant recreation, instead of having to engage in a brief struggle against overwhelming odds, the while seeing his family dragged down to poverty and want. In the model village the amenities of life are such that the wife and child are protected from all massive infection, and in time the latter will be free to compete in the world at large, unhandicapped by intervening years of want, malnutrition, and consequent lowered resistance. There may be little hope of altering at a stroke of the pen imperfect economic conditions in the world at large, but we now have ample evidence that small communities may be, and have been, inaugurated, where the conditions of existence may in time constitute a model for the workaday world outside. Such communities realise the dream of all social workers, and embody the aim and end sought by the consumptive workers of the world, who desire the priceless privilege of living in surroundings that will compensate for their segregation, while helping to protect the communities outside against dangerous sources of infection.

*Essential Features of Consumptive Industries.*

The features essential for the industries specially run for consumptives are many and complex, but the idea that such industries can be only those carried on in the open air must be abandoned as a practical proposition, and this for one reason among others, that enormous tracts of land would be required on which to carry them out. On an acre of ground, unless very highly and intensively cultivated, few people can be employed. An ordinary farm of 200 acres would afford employment for a number of hands infinitesimal as compared with the number of cases awaiting admission. It is, therefore, of primary importance that industries should be started capable of absorbing a greater number of workers per acre of ground. It is accepted that it is impossible to train a

man in a new trade in the short space of time allotted, so it is obviously inadvisable to select an occupation in which elaborate training must of necessity take place; but from the munition works we have acquired experience which should be applied with great success in the employment of the consumptive. Strenuous and prolonged physical manual labour must be avoided and the use of modern machinery enables us to do away with such severe manual toil. It is now no longer necessary to set consumptives to work at carpentry, say, with a plane and a saw, and instruct them in the performance of labour which in all modern businesses is done by machinery. (Little wonder that on the old methods our goods could not compete in the open market.)

In a well-ventilated workshop with good aspect, fitted with modern machinery, the hours of toil regulated to a nicety by a sympathetic management, it is possible for consumptives to earn a reasonable rate of wages. That the wage earned is insufficient to keep the man and his family goes without saying, for, as already pointed out, a full trade-union rate of wages for the short hours worked is insufficient to provide for that standard of comfort which is essential for the well-being of the patient. We are dealing with the 50 per cent. capacity man, and no speeding-up machinery brought into play can do other than leave the percentage unaltered, but it does relieve the patient of much too strenuous exertion. The State must come to the rescue, and for its protection against infection must contribute a subsidy equivalent to some percentage of the patient's earning capacity. When once an industrial colony has been started it will be possible to employ numbers of subsidised patients at various trades, and an encouraging vista of employment will be opened up to our consumptives. All we have to do is to find out and provide the necessary conditions, and make rules and regulations whereby the most suitable working hours are ensured and excessive toil eliminated. Given these things, the labour of the consumptive may be made so remunerative that, while some subsidy will be necessary, it need not be large and will be well applied, especially when the advantages to the general community are taken into consideration. These applied elementary principles of colony treatment, common to all workers amongst the tuberculous, indicate a distinct advance along lines hitherto but little explored. Organisation is needed in order that these principles may be applied logically in the domain of practical politics in the near future. Here we must have organisation of the home life; there must also be a coördinated attack upon the disease, its effects and its causes, primary and predisposing; a full appreciation of the factors in the spread of the disease; and a realisation of the fact that all measures to be successful must be continuous, well-directed, and prolonged. Sir Arthur Newsholme, in his foreword to Dr. Chapman's report on colonies, appreciates the position exactly, except that he does not refer to the control of infection outside the home. "The greater part of the consumptive's life is spent at home, often under unsatisfactory conditions both for the patient and his family, and the supervision of his home life by the tuberculosis officer and the health visitor, even when this is frequent and sympathetic, does not completely meet his needs. If the patient is to have the best possible prospect of recovery, and if his family are to be safeguarded against infection, in many cases he will need (a) improved housing; (b) occupation adapted to his physical capacity. &c.; (c) the family income will need to be supplemented. These requirements for many patients have not hitherto been met."

*Some System of Segregation Required.*

They have not been met, and for the reasons given in the earlier part of this paper they are not likely to be fully met until some system of segregation is thought out and organised. The problem of occupation under private employers working for profit is not likely to be solved; it is impracticable, and, moreover, it may be prejudicial to the health of the other workers to have subsidised consumptives working alongside the non-tuberculous. With the provision of separate workshops and separate dwellings the difficulties, though not by any means removed, are minimised. Indeed, our thoughts directed into this channel, the colony idea acquires an entirely new significance. Formerly it meant the advocacy of open-air occupation, and the provision of those special conditions that were available for the wealthy few: it is not until we can get the public to view the matter from an entirely different angle that the full significance of the new colony idea becomes evident. From the fresh stand-

<sup>2</sup> Varrier-Jones: "A Plea for the Consumptive Soldier," Reveille, No. 2, 1918.

point facts which seem to have no place in our system assume a new importance, and fit in with the general scheme, helping to bind it into a concrete whole.

No scheme for the control of the tuberculous can be regarded as satisfactory which does not embrace the whole life of the consumptive patient. But what scheme can control the whole life of a consumptive in our crowded cities, and where can an organisation be found to throw its tentacles into every yard and alley?

#### *Recommendations of the Inter-Departmental Committee.*

In the past we have gained a knowledge of the facts, but we have failed to view them from the right angle. Turn the picture round; let us get rid of preconceived notions, and build on the firm rock of experience and tried methods. Then, and then only, will progress be made and success attained.

We now note with interest that the Inter-Departmental Committee on Tuberculosis appointed in April, 1919, "to consider and report on the immediate practical steps which should be taken for the provision of residential treatment for discharged soldiers and sailors suffering from tuberculosis and for their reintroduction into employment, especially on the land," has, as a result of its inquiries, and reporting very promptly, recommended that the Papworth Colony, with its various departments, should be adopted for development in various centres all over the country. That it may be improved and developed we recognise very fully. That there are difficulties to be overcome we have ample experience. But that it is based on sound lines we are satisfied, and for this reason, and not because it has been built up in Cambridge; we welcome the recommendations of the Inter-Departmental Committee.

## TREATMENT OF SEPTIC WOUNDS BY IONISATION.

BY F. W. BAKER YOUNG, M.B., CH.B. MANCH.,  
CAPTAIN, R.A.M.C. (T.F.); HONORARY ASSISTANT SURGEON, CANCER  
AND SKIN HOSPITAL, LIVERPOOL.

CASES were treated at a general hospital at the request of Colonel G. W. Crile, M.C., U.S.A., to demonstrate the effect of ionisation in rendering wounds aseptic for delayed primary suture.

#### *Account of Experiments.*

The action of the metallic ions on suppurating wounds, particularly zinc, is well known, and I decided to try the effect of the chlorine ion. Several laboratory experiments were carried out to show that the chlorine ion was detrimental to the growth of bacteria. Although several observers have described the effect of the electrolytic current on bacteria, I can find no description of apparatus. Accordingly apparatus were devised for my purpose. In one experiment a glass tube about 1½ inches in length is closely fitted at each end with a carbon electrode which is fitted into a rubber tube. The rubber tube acts as a cork and as a non-conducting cover for the wires leading to the milliamp. meter. Before use the rubber, glass tube, and electrodes were sterilised by boiling. The solutions to be tested were placed in the glass tube, which was then placed in a water bath kept at blood temperature by a lamp.

*Experiment 1.*—An emulsion of *Staphylococcus aureus* and *albus* was prepared with a normal saline solution at blood heat. The electrode and rubber tube were removed from one end of the glass tube and the tube was almost filled with emulsion. A drop was then taken with a loop and smeared on agar-agar in a test-tube as a control. The electrode and rubber tube were then placed tightly into the glass tube and the whole placed in the water bath. Currents were passed of 5 ma. for 5 minutes, 10 minutes, and 15 minutes respectively. At the end of each period of time a drop was taken by a platinum loop dipped into emulsion, and a smear was made on marked tubes containing agar-agar.

A second series, in which 10 ma. were passed for 5 minutes and 10 minutes respectively, was also taken. The tubes were then placed in an incubator for 18 hours with the following result:—

*First series. Tube A control.*—Profuse colonies of *Staphylococcus aureus* and *albus* covering entire media.

*Tube 1. 5 ma. × 5 minutes.*—Profuse colonies of *Staphylococcus aureus* and *albus*, not so abundant as on control.

*Tube 2. 5 ma. × 10 minutes.*—Colonies of *Staphylococcus aureus* and *albus* discrete, small, and fewer than in tube 1.

*Tube 3. 5 ma. × 15 minutes.*—Agar-agar practically sterile, only one small colony survived.

*Second series. Tube 1. 10 ma. × 5 minutes.*—Colonies discrete and identical in appearance with tube 2.

*Tube 5. 10 ma. × 10 minutes.*—Agar-agar sterile. No growth.

*Deduction.*—Electrolysis with sodium chloride will inhibit the growth of *Staphylococcus aureus* and *albus* with a short exposure and with a low current strength. 10 ma. given for 10 minutes is sufficient to render a culture sterile.

*Experiment 2.*—A microscope slide is prepared with a plasticine cell and the walls of the cell are perforated by the platinum wire. A drop of emulsion of *Staphylococcus aureus* and *albus* was placed in the cell with a few drops of normal saline. The cell was then placed on a warm stage, which was kept at blood heat by siphonage of warm water. The electrodes were then connected with the milliamp. meter. The warm stage was then placed on a microscope stage and a current of 2 ma. passed. There was an immediate activity of the cocci and a general flocking towards the positive pole. The current was increased to 4 ma., when the bacteria arranged themselves in apparently three layers around this pole. At the end of five minutes all movement of cocci had ceased.

*Experiment 3.*—Similarly prepared with plasticine cell. A smear of living culture of gonococcus was placed in cell. A few drops of fresh human blood were then dropped on the gonococci and the whole covered with a cover-glass and placed on a warm stage and connected up with the milliamp. meter as before. 0.5 ma. was then passed for 10 minutes. Gas was given off at the negative electrode and a small drop of blood escaped at the point where the electrode passed through the plasticine. The cover-slip was removed and the plasticine lifted off slide. The blood clot was carefully washed off with normal saline, the slide was then fixed with heat and stained with methylene blue, covered with a slip, and examined under high power with oil immersion. It was observed that complete phagocytosis had occurred. Practically every leucocyte was crowded with gonococci. A few gonococci were extra-cellular.

*Deduction.*—Phagocytosis is probably stimulated by a small current passed for a short time.

#### *Clinical Results.*

I determined to use sodium chloride in treating wounds as likely to cause less irritant effect on the tissues than the metal ions. The average administration was 10 ma. for 20 minutes daily, the wound afterwards being dressed with sterile gauze soaked in normal saline. No other antiseptic was used. In a few cases of cellulitis where the oedema was very marked one hot pack was applied at night-time. By this means the skin was never rendered sodden.

Six cases were treated and sutured, 4 with success and 1 with only partial success. The sixth case broke down and was evacuated to England owing to pressure on hospital accommodation.

Twelve cases of cellulitis were treated, and these were entirely successful. The pain was considerably lessened, and the final result, even in cases in which tendon and tendon-sheaths were involved, showed fewer signs of contracting scar tissue than generally occurs following septic infection of the tendon-sheaths.

Other types of cases were through gunshot wounds of extremities.

Three cases were treated with a view of preparing the surface for skin-grafting, and in one case periosteum was grafted on an exposed tibia.

Four cases in which a joint was exposed and septic were treated, one with complete success. The remaining three cases (two elbows and one knee) had multiple wounds, and the patients were in such a feeble general condition that treatment with ionisation was not carried out on account of the lowered vitality due to multiple wounds.

*Technique.*—Where it was possible to immerse the limb the injured part was placed in a porcelain bath with a carbon electrode. The inert electrode was placed either under the patient's buttocks or strapped to an uninjured limb. Where immersion was impossible several thicknesses of lint were wrung out in a 1 per cent. sodium chloride solution and Carrel's tubes were placed in contact with the wound and covered with the lint, leaving the open end of the tube free. An electrode was then banded to the lint. By means of the Carrel's tubes it was possible to keep up a fresh solution through a sterile glass syringe while the treatment was carried on.

Several cases were examined bacteriologically; examination was made previous to the operation. [A series of cases was here given supporting the statements in the text.]

#### Conclusions.

Ionisation with chlorine or zinc does not possess any advantage over other methods for sterilising a wound for the purpose of delayed primary suture.

Cases of cellulitis show a marked improvement when treated with ionisation, both in the relief experienced by patient and in the final result, which in every case treated was extremely satisfactory, cicatricial contractures being practically unseen.

The fact that one septic joint recovered indicates that the treatment is well worth trying in similar cases.

My thanks are due to Lieutenant-Colonel R. B. Ainsworth, D.S.O., R.A.M.C., for allowing me to carry out these investigations, and to Colonel Crile for supplying the cases and apparatus and for his extremely helpful suggestions and advice.

## Clinical Notes :

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### AN UNUSUAL CASE OF RETROVERSION OF THE GRAVID UTERUS.

BY R. BURTON ECCLES, L.R.C.P., M.R.C.S.

THE following unusual case of retroversion of the gravid uterus deserves record :—

I was sent for to attend a woman, the message saying that a piece of howel 10 inches or more in length had been protruding for a week, and there had been no evacuation of the howels for the same period, although large doses of castor oil, cascara, and Epsom salts had been taken.

On arrival I found the patient, a woman, aged 27 years, in bed, looking very ill, and complaining of great pain in the back and lower part of her body. The history I got from her was that 14 days previous to my coming she had a sudden pain in the lower part of the body and the back, with frequent desire to micturate. Then the abdomen gradually began to enlarge. Though she had constant dribbling for 14 days, she had been able to pass, each day, a few ounces of clear-coloured urine, and she passed clear urine while I was in attendance.

On examination I found the abdomen very greatly enlarged, giving me the impression at first sight that she was probably in the eighth or ninth month of pregnancy. The body was hard and dull on percussion, the dullness extending above the umbilicus to the ensiform cartilage. The right thigh and leg were enormously swollen and oedematous, also the vulva, the right labia forming a large cushion reaching up to and completely obliterating the anal aperture; serous fluid was oozing from both labia. I then passed a catheter and drew off 104 oz. of dark bloody urine. Per vaginam I felt, with great difficulty, the cervix pushed high up behind the symphysis. The posterior fornix was obliterated by a large, elastic, globular swelling, which filled up the vagina. Per rectum I felt a large substance, which was, in fact, a retroverted uterus. I ascertained from the patient that she had last menstruated three and a half months ago, and came to the conclusion that I had an incarcerated, retroverted, gravid uterus to deal with.

I first tried to replace the uterus manually and failed. As I did not care to use bullet forceps on so oedematous and congested a cervix, I replaced the uterus by the knee-elbow position, the patient at once remarking, "What a great comfort," and that she was now free from pain. I then introduced a Smith-Hodge pessary to keep the uterus anteverted. There was complete atony of the bladder, and a catheter was passed every six hours for eight days. A mixture of hexamine, sodium benzoate, and tincture of nuxvomica was given every four hours.

The patient made an excellent recovery. At the end of the fifth month of pregnancy I removed the pessary. Four months afterwards she gave birth to a fine, healthy male child, the labour being quite normal.

The points in this case, unusual in my experience of country practice, are the absence of serious complications, such as sloughing of the bladder or septic cystitis, and the fact that the woman went on to full term of pregnancy and gave birth to a healthy child.

Driffield, East Yorks.

### SPONTANEOUS CURE OF STRANGULATED INGUINAL HERNIA.

BY W. FLETCHER STIELL, L.R.C.P., M.R.C.S.,  
RESIDENT MEDICAL OFFICER, COUNTY HOSPITAL, LINCOLN.

I AM taking the opportunity of recording this case, not as a plea to wait, watch, and expect such a happy result to ensue from so serious a condition, but more as a surgical curiosity.

A man, aged 37, had been suffering from a swelling in the left groin for about five years. He had during this period consulted several doctors, who had unanimously wisely advised cure of the hernia by operation. The patient was, however, of the procrastinating type and had failed to follow the advice given. On Feb. 4th, 1918, the patient attended the Lincoln County Hospital on account of a painful swelling in the left groin. He gave the following history :—

*History.*—He had noticed the swelling for about five years, he "knew it was a rupture," and as he had never had any difficulty in effecting reduction of the hernial contents, did not think an operation necessary. In December, 1917, the tumour had suddenly increased in size, had become both painful and tender, and could never again be reduced. There was at that time some generalised abdominal discomfort, but no vomiting, constipation, or other symptoms to suggest any intestinal obstruction.

At the actual time of admission to hospital all abdominal symptoms had disappeared and there were no abnormal physical signs in the abdomen. In the region of the left cord, just below the external ring, there was a well-defined, hard, non-cystic tumour, which was neither painful nor tender. The mass was fairly freely movable from side to side, but was fixed in a vertical direction. It was found impossible therefore to reduce it, either into the abdomen or into the scrotum. The testicle itself was unaltered, and a normal vas deferens could be traced upwards behind the tumour.

*Differential diagnosis.*—The differential diagnosis at this stage of examination rested between : (a) an omental plug in an incarcerated inguinal hernia; (b) fibroma of the cord; (c) an organised hæmatoma of the cord from forcible attempts at reduction by taxis on the part of the patient himself.

*Operation.*—Operation was performed on Feb. 5th, 1918. The actual technique and procedure of the operation were in a large measure similar to an ordinary radical cure for inguinal hernia, so that it is unnecessary to describe them in detail. The tumour was occupying the inguinal canal with the aponeurosis of the external oblique and the external abdominal ring stretched tightly over its anterior surface. The tumour itself was everywhere surrounded by a thickened peritoneal investment, to which it was closely attached by old-standing and somewhat vascularised adhesions. The various constituents of the cord were lying posterior to the tumour, and were abnormally adherent to its peritoneal lining. When traced in an upward direction the peritoneal coat of the tumour gradually merged into a small strand of dense fibrous tissue, and the internal ring was solidly and absolutely occluded. The cord was thoroughly isolated, the tumour, together with its peritoneal investment, removed, and the operation completed, as in Halstead's method of radical cure. Convalescence was uneventful and, although no peritoneal neck to the sack could be ligatured at the internal ring, there has been no recurrence of the hernia after 18 months.

*Microscopic examination.*—Microscopic examination of the tumour was performed by a pathologist, who was intentionally given no information of the case, and his findings are therefore of interest. He stated that "this is a mass of fat showing fibrous alveolation. It is undergoing fibrous degeneration and inflammatory infiltration. No evidence of tubercle or new growth. There is no evidence to show how it has originated."

*Remarks.*—Taking into consideration the history of the case, the findings at the operation and the histological examination, there can be little doubt that the tumour owed its origin to an omental plug in the strangulated inguinal epiplocele, which had undergone a process of aseptic necrosis at the internal abdominal ring, with subsequent complete stenosis of the ring. The tumour, therefore consisted of a mass of omentum which, at the time of operation, possessed no actual anatomical connexion with the main mass of the great omentum.

For permission to publish this case I am much indebted to Major D. J. G. Watkins, R.A.M.C. (T.F.), who performed the operation.

## Reviews and Notices of Books.

*War Neuroses and Shell Shock.* By Sir FREDERICK W. MOTT, M.D., LL.D., F.R.S., Brevet-Colonel, R.A.M.C. (T.), &c. With Preface by the Right Hon. CHRISTOPHER ADDISON, M.P., Minister of Reconstruction. London: Henry Frowde and Hodder and Stoughton. 1919. Pp. 348. 16s.

WITH a good deal of Sir Frederick Mott's excellent and comprehensive volume on war neuroses the profession has already become acquainted through previous publication in the form of lectures or otherwise, not infrequently in our own columns. To have at hand, however, a useful "body" of doctrine on the functional neurology of war is almost a *sine qua non* for the practitioner, in view of the large number of functional cases still requiring at least a modicum of treatment. In Sir Frederick Mott's book will be found all he needs on the practical side, for treatment is discussed in detail, together with clinical studies of the multifarious types of war neuroses and interesting analyses of the pathogenesis of such disorders. The author is catholic enough to appreciate the value of the Freudian theory where affections of the psyche are concerned, but he points out the inadequacy of certain Freudian contentions in the case of the typical war neurotic, and emphasises the importance of the commotional element, introducing material that formed part of his Lettsomian lectures<sup>1</sup> on "The Effects of High Explosives on the Central Nervous System." He goes beyond the commotion, however, to elaborate the greater importance of the emotional shock in the perpetuation of symptoms, and furnishes numerous confirmatory clinical illustrations. A section of the book is devoted to study of the phenomena of gas poisoning, both on the clinical and on the pathological side. We do not suppose the practitioner is likely to observe any variety of symptom or symptom-complex of a functional sort, nervous or mental, which is not at least touched on in this book; nor need he be at a loss how to deal with such cases, for Sir Frederick Mott devotes many pages to a discussion of the means of promoting convalescence and of establishing an atmosphere of cure.

In comparatively small compass the results of five years' familiarity with the problems of functional war disorders have been garnered, sifted, and offered for consideration, and we agree with Dr. Addison that a book which is the outcome of such unusual experience cannot fail to be of great value.

*Psychoses of the War, including Neurasthenia and Shell Shock.* By H. C. MARR, Lieutenant-Colonel, R.A.M.C., M.D., Neurological Consultant to the Scottish Command, &c. London: Henry Frowde and Hodder and Stoughton. 1919. Pp. 292. 16s.

Dr. Marr bases his interesting volume on material derived from the observation of no less than 18,000 officers and men, of whom approximately one-half were sufferers from shell shock and neurasthenia, and one-half from more definite mental disorders. The book, however, is not a mere précis of information on war psychoses, inasmuch as its author devotes some space to general observations on the pathogenesis of mental disease, to its types and their clinical expression, to cerebral anatomy and mental pathology, and to infantile mental deficiency. Further, there are sections on the classification of mental affections, on mental case-taking, and on the cerebro-spinal fluid. Not a few of the useful clinical photographs reproduced are of cases of mental disorder in the female sex and of mental defectives who can never have been in the Army. We might, in fact, suggest to Dr. Marr that his title is rather misleading and unnecessarily restricted; his book really constitutes a concise and readable compendium of mental diseases, illustrated by a large number of clinical records derived from military material.

Dr. Marr divides his subject into the four main groups of infantile mental deficiency, adolescent mental enfeeblement, toxic (confusional) psychoses, and organic psychoses. The respective percentages of these in 3755 cases of mental affection in soldiers were 42.31, 8.92, 36.73, and 12.04. It is somewhat surprising to learn that 42 per cent. of the

soldiers admitted to mental hospitals were found to have been weak-minded from infancy, but an adequate explanation is forthcoming in the fact of the capacity for manual routine labour of all kinds exhibited by the mental defective, at least under direction and supervision; their docility and usefulness leads to their being employed on work for which they are quite unsuitable, with the inevitable result. Dr. Marr charitably exonerates the authorities from blame; the mental defective shows, as a rule, no gross bodily physical defect, his mental state does not obtrude itself except in the face of responsibility, and in doubtful cases expert medical investigation is not likely to be always at hand. His second group comprises primary mania, melancholia and dementia, as also alternating insanity and idiopathic epilepsy—conditions in which inherent neuronic weakness is unable to resist the united strain of adolescence and military service. The third group, the second largest, includes the psychoses of both known and unknown toxic agents, the presence of which in the circulation "acts as a veil between the mental functions and the external world." The fourth group deals mainly with neurosyphilis, but also with trauma, arteriosclerosis, and cerebral tumour.

Dr. Marr's selected clinical cases are described in a fresh and informative fashion, which adds to the attractiveness of a useful, unpretentious exposition of the main facts of mental disease, wonderfully complete for its size, well illustrated, and with a good index.

*Psycho-Analysis and its Place in Life.* By M. K. BRADBY. London: Henry Frowde and Hodder and Stoughton. 1919. Pp. 266. 8s. 6d.

Miss Bradby's standpoint is that of the trained psychologist, who is also a humanist, and impressed by the possibilities of life in general which, she believes, seem to open up as a consequence of the discoveries in the realm of thought of Freud and Jung. Her rôle is, in part, that of the expositor, to the educated man or woman, of the meaning of psycho-analysis, but she also makes a persuasive appeal to the psychologist to interest himself at least as much in feeling and willing as in knowing, and to the Freudian psycho-analyst not to ignore such ruling passions of humanity as are not embodied in sexuality.

The reader will find much that is admirable in Miss Bradby's presentation of her subject, which is marked by erudition and independent thinking and by a freshness of exposition and originality of view which will impress those of us who may confine our attention too strictly to the volumes of the medical profession proper.

Miss Bradby at the outset correlates the knowledge of the unconscious mind derived from psycho-analytic investigation with that of the nature and development of mind in primitive man and with our knowledge of the mind of the child. The mode of working of the unconscious mind is sketched and Freudian theory more or less accepted. The Freudian interpretation of dreams is favourably reviewed and various dreams, historical and private, are analysed. The author then considers the application to social and individual conduct of the knowledge of hidden and unconscious motives acquired by psycho-analytic procedures, and ends on a note of enthusiastic hope for future progress, especially in the sphere of education, as the result of such self-knowledge.

It will be understood that Miss Bradby deals mainly with the application of psycho-analysis to the normal mind, and only incidentally, and, we may suppose, at secondhand, with mental disease. She is not on sure ground when she speaks of "perfectly natural normal homosexuality," repressed into the unconscious "in sensitive and upright minds, with results that are always injurious to health and often to sanity." Assuming the facts, they are capable of a quite other, medical, interpretation. Other statements that have a bearing on medicine require more substantiation than is given them, which is perhaps unfortunate, for the lay reader may be inclined to accept as proven what are not specified by Miss Bradby as psycho-analytic assumptions. More generally we get the impression that there is a certain tacit disregard of the significance of the conscious life, as being of less value than unconscious mental activity, and we feel that there is also an unwitting minimising of moral upbringing and the formation of good habits by influence from without, as though knowledge of the unconscious self were somehow to make men all that they should be. But is there any dynamic force in

<sup>1</sup> THE LANCET, 1916, I., 331, 441, and 545.

such self-knowledge, assuming it can be acquired by psycho-analysis? Has it any driving power for good as against evil? Will the dragging of unconscious motives and impulses into the full light of consciousness of itself make us pursue the good? It may be pointed out, further, that springs of action are far from being always as deep down and as hidden as Miss Bradby's reading of the Freudian position suggests.

*What is Psycho-Analysis?* By ISADOR H. CORIAT, M.D., Physician for Diseases of the Nervous System, Boston City Hospital. London: Kegan Paul. 1919. Pp. 124. 3s. 6d.

FROM the preface we learn that this little volume, on the question-and-answer system, is intended for "physicians, clergymen, social workers, and laymen" who are interested in psycho-analysis from the point of view of its aim, purpose, and field of usefulness as a therapeutic procedure. The deduction is allowable that Dr. Coriat sees no disadvantage in individuals becoming familiar with psycho-analysis (as a therapeutic procedure) who can have no trained knowledge whatever of organic or functional nervous disease. It appears to us that the important distinction between psycho-analysis as a method of investigation of the mind, normal or abnormal, and as a means of treating functional nervous disorders, is thereby in danger of becoming eliminated. Many psychologists, many workers in cognate branches of science, are legitimately studying the applicability of Freudian technique to their own subject, but it is a long step from this to the handling of the mind diseased, unless we are to be content to let the opportunity slip and allow non-medical intervention in therapeutics an even larger scope than it has already. No one who is familiar with the results of misdirected, because ignorant, lay treatment can view the prospect with equanimity.

Dr. Coriat follows conventional Freudian doctrine in his little sketch, minimising the difficulties and avoiding as far as may be the contentious aspects. Like Freud, he maintains that under no circumstances does the element of suggestion enter into psycho-analysis, notwithstanding the obstacles in the way of the acceptance of this statement. It is a counsel of perfection to say, as Dr. Coriat does, that "no explanations or suggestions are made to the patient during the course of treatment," for in another section he declares that "the ethical value of psycho-analysis depends upon telling a patient the truth," in other words, explanation. In one answer we find the statement that "libido means vital energy or instinct; it is not always sexual, since the instinct may be hunger or nutritional." Two pages farther on we read that "the sexual instinct displays itself very early in the child, first as the sucking or nutritional instinct"—a contradiction illustrating the preconceptions of the crystallised Freudian mind. We are glad to be assured, however, that "if psycho-analysis be properly carried out it refers less to sexual activities than does the usual medical history of an organic illness."

*Shell Shock, Commotional and Emotional Aspects.* By ANDRÉ LÉRI, Professor in the Faculty of Paris. With Preface by Professor PIERRE MARIE. Edited, with Preface, by Sir JOHN COLLIE, M.D., C.M.G. London: University of London Press. 1919. Pp. 249. 7s. 6d.

WE gave a favourable review of this book on its original appearance in the Horizon Series of military manuals published by Messrs. Masson, of Paris. It is, in our opinion, one of the very best of all the productions bearing on shell shock, and we are confident that its reception in English form will corroborate this opinion. When Charcot was congratulated on the lucidity of his lectures by a foreign confrère well qualified to do so, he replied deprecatingly: "Ah, Monsieur, it's our language." It is not, however, a question of language merely; the Gallic mind has the power of expressing itself with unusual clarity, consecutiveness, and conciseness. All these qualities are found in Professor Léri's excellent monograph.

*Vegetative Neurology: The Anatomy, Physiology, Pharmacodynamics, and Pathology of the Sympathetic and Autonomic Nervous Systems.* By Dr. HEINRICH HIGIER, of Warsaw. Authorised translation by WALTER M. KRAUS, M.D., New York. New York: Nervous and Mental Disease Publishing Co. 1919. Pp. 144. \$2.

Dr. Higier's monograph appeared originally in the *Ergebnisse der Neurologie*, which came to an untimely end,

after only three or four issues had appeared, on the outbreak of the war. The edition published in English is a faithful translation of the original, but the illustrations are not, this time, in colours—somewhat of a drawback, as some of them are very complicated. No student of neurology wishing to keep abreast of knowledge should be without this monograph, in which the author, collating from the widest sources data bearing on his subject, has organised his material into a *revue d'ensemble* which is a model of what such reviews should be. It is not a rival but complementary to such a study as Gaskell's "Involuntary Nervous System"; it does not contain personal original work, but, on the other hand, it represents a laborious marshalling of facts and an able selective skill on the part of the author. The translator has spared us Americanisms, but a painful number of slips have been allowed to escape the proof-reading—e.g., sphincter anus, rami communicanti, was deferens and prostrate, nerve bundles or plexi, different than, mucus colitis, &c. "Unreactibility" (p. 79) is not an Americanism: it is a monstrosity.

*A Conspectus of Recent Legislation on Venereal Disease in the British Dominions and United States of America.* By DOUGLAS WHITE, M.D. London: Published by the National Council for Combating Venereal Disease.

WE welcome this pamphlet not only on account of the systematic presentation of the recent legislation on venereal disease in the countries mentioned, but also by reason of the interesting statements as to the results which have accrued from such legislation.

This valuable pamphlet, under the heading of "Conclusion," contains some most suggestive remarks by Dr. White on the subject of legislation in Great Britain, with reference to the Act of Parliament of 1917. "How much further, and in what direction," he pertinently asks, "are we prepared to move"? He then considers the questions of: (1) notification; (2) penalisation of the conscious transmission of disease; (3) the active repression of prostitution; (4) the safeguarding of marriage against disease.

Dealing with the subject of prophylaxis in the U.S.A., Dr. White writes: "No reference is made to this method in any laws or regulations. All the bureaux of health, who have replied to a query on this matter, express distrust and disapproval of prophylactic 'packets' as likely to defeat the object in view. Some go further and include in their disapproval 'early preventive treatment.' Some express approval of the latter method, but it has not apparently been instituted, unless sporadically, except by the military authorities in the area of the camps. In these, however, good results have been obtained."

The author has dealt successfully with each of the four subjects indicated above and may be congratulated on the attainment of his professed objective—namely, to give information succinctly and to stimulate thought.

*Injuries to the Head and Neck.* By H. LAWSON WHALE, M.D. Cantab., F.R.C.S. London: Baillière, Tindall, and Cox. 1919. Pp. 320. 15s.

THE title of this book is misleading, as the injuries described are, without exception, those due to gunshot wounds about the head and neck; injuries such as those found in civilian practice are not dealt with. Injuries to the vault of the skull, the brain, and the eye are not described, the book dealing only with injuries to those parts which come within the province of the oto-laryngologist; to which is added a chapter upon prosthesis and plastic operations after severe injuries to the face and jaws.

The book contains full records of numerous interesting cases, which illustrate the signs, symptoms, and method of treatment of injuries in this region of the body. This is not a text-book for students, but Mr. Whale has produced a volume which should appeal to the practitioner who is interested in the broad lines of treatment which have been employed in the treatment of war injuries of the head and neck. The plastic work upon the face is new, describing the procedures necessitated by war conditions, but the recognised methods of civil surgery have been modified to suit the special cases treated. The book is written in a pleasant, discursive style, and is well and fully illustrated.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 20, 1919.

## Malaria in England.

MALARIA at one time was endemic in England, and traces of its presence could still be found in some London hospitals as late as the early "seventies," patients being sometimes admitted from Essex and other districts for the treatment of enlarged spleens or "ague cakes." The prevalence of laudanum-drinking among the agricultural population of the low-lying districts of Lincolnshire as late as 50 years ago was explained as being due to the need for taking an anodyne to mitigate the discomforts of their recurring attacks of ague. Of late years, however, there has been a general impression that draining and bringing under cultivation of much marshy and waste ground has led to the disappearance of endemic malaria in the affected parts of England. Up to the outbreak of the war little notice was taken of imported malaria cases, it being assumed by many persons that our local mosquitoes were not likely to act as carriers of the infection. But when our soldiers began to be invalided home as the result of malaria contracted mostly in the Eastern war zones, and especially in Macedonia, the Local Government Board entered into communication with the medical departments of the Navy and Army in order that joint action might be taken to meet the danger. Surgeon-Captain P. W. BASSETT-SMITH, directed measures on behalf of the Navy, and Sir RONALD ROSS, consultant in malaria to the War Office, on behalf of the Army. The measures against civilian infection were directed by Lieutenant-Colonel S. P. JAMES, adviser on malaria to the Local Government Board, and Lieutenant-Colonel E. WILKINSON, late Sanitary Commissioner for the Punjab, medical inspector of the Local Government Board, with whom was associated a skilled entomologist, Mr. A. J. GROVE, M.Sc.

A report on malaria in England during 1917 has already been published. Quite recently another report,<sup>1</sup> for 1918, has been issued with an introduction by Dr. G. S. BUCHANAN, first assistant medical officer to the Local Government Board, summarising clearly the results of action taken against the risks of a spread of malaria in this country. From this report it appears that there are at least three species of anophelines, the malaria-carrying mosquitoes, to be found at present in this country, and it is stated that evidence has been found that there are a few areas in England where a mild form of true indigenous malaria still persists. Special inquiries were made into the cases of subjects who were said to have contracted malaria in England during 1917 and 1918. The total number of such cases was 330, of which 38 occurred in the Navy, 224 in the Army, and 68 in the civil population. Of the civil cases 42 occurred in 1917 and 24 in 1918; the majority in both years occurred in

the county of Kent, in an area at the mouth of the Thames, including the towns of Sheerness and Queenborough. All the locally contracted malaria cases were due to infection with the benign tertian parasite, and none died. In the military malaria cases, in which the infection had been contracted in England, their source of origin was attributable to the presence in their immediate neighbourhood of relapsing cases of malaria among soldiers invalided home from the Eastern war zones. In the naval cases the origin was not in all cases so obvious, but some of them occurred in the Kent area already mentioned. Among the civilian population the origin of the cases was generally due to relapses in returned malarious soldiers; but a local outbreak in the civil population of Queenborough included cases whose illness appeared to be attributable to infection from civilians in their immediate vicinity. The clinical characters of these last-mentioned cases were less severe than those in which the infection was derived from returned soldiers, and this suggests that they were possibly due to an indigenous strain of the benign tertian parasite instead of the more virulent strain recently imported from the Eastern war areas. There is a probability that the hot weather in September of the present year may favour the breeding and development of anophelines in districts which have not as yet taken satisfactory steps to reduce the breeding-places of these mosquitoes. We understand that in 1919 both at Sheerness and Queenborough malaria cases, locally contracted, have again been reported. In the Fletton urban district, in the county of Huntingdon, not far from Peterborough, a boy who had never been out of the district is reported to have developed an attack of malaria. It is probable that other instances not recorded as yet in the press have also occurred.

The action taken by the Local Government Board to prevent the spread of malaria in the civil population seems to have been sufficiently comprehensive. Its policy was based primarily on the early detection of all malaria cases and carriers, followed by thorough treatment, protection from mosquitoes, along with special supervision and control. In selected areas this action was supplemented by anti-mosquito measures directed specially against the breeding-places of these insects. Notification of malaria was made compulsory in certain districts. Since the Armistice other measures have been added, in consultation with the Ministry of Pensions and the National Health Insurance Department, for the treatment of malaria in demobilised men. A pamphlet entitled "Suggestions for the Care of Malaria Patients," was prepared by Lieutenant-Colonel JAMES, in collaboration with Sir RONALD ROSS, and this was distributed to medical practitioners throughout the country. In January, 1919, the Local Government Board issued an Order, "Public Health (Pneumonia, Malaria, Dysentery, &c.) Regulations, 1919," which, among other things, imposed on local authorities and their officers certain new powers and duties in regard to malaria prevention. All practical assistance was given by the expert officers of the Local Government Board to medical officers of health and medical practitioners; in all cases where indigenous malaria was suspected and where no other arrangement had been made for the examination of blood films, this duty was undertaken by the experts belonging to the Board's Medical Department.

## A Shorter Working Day.

AT the meeting of the British Association interest was manifested by a large attendance, which overstrained the accommodation provided, in the possibilities of reduction in hours of labour, with special reference to Lord LEVERHULME'S proposal of a six-hour day. The subject was introduced by Dr. H. M. VERNON, who spoke from his unique knowledge of output under different periods of employment, as ascertained by him in a variety of industries during the war on behalf of the Health of Munition Workers Committee, and since then for the Industrial Fatigue Research Board. Mr. SARGANT FLORENCE told of the work now being carried on by the National Research Council in the United States; while Professor E. L. COLLIS, Sir HUGH BELL, and Professor A. D. WALLER also presented different aspects of the case. Every social movement which affects a considerable portion of the community calls for close attention, but the present position in the industrial section of the community, which forms so large a portion of the whole, and upon which the whole is finally dependent, requires to be watched with particular interest by the medical profession. The workers are demanding and are obtaining a great reduction in their hours of labour with no reduction in their earnings. These hours have up to the present remained (except for miners) practically unaltered since 1850, when they were limited by the Factory Acts to 56½ per week for textile workers and 60 for other operatives; these limits, it is true, only apply to "protected" labour—i.e., juveniles and females—but the hours of the unprotected adult male have been largely determined by these legal limits.

Every community is alive and reacts as a living organism to the influences to which it is subjected; and its reactions are to be measured by the collective behaviour of the units of which it is composed, as indicated by vital statistics. Such records show that epidemics of disease, like influenza or plague, come and go, ruffling the waves of the advancing or receding tide of health, but not materially affecting the total rise or fall over long periods. Three main influences affect life—the air we breathe, the food we eat, the work we do. The effect of the air does not now concern us, although data are accumulating which support the contention that impurities poured into the air of great cities and industrial centres have an important and harmful influence. The importance of the food supply has long been recognised, particularly since MALTHUS early last century pointed out that increase or decrease of population followed the food-supply rather than the birth-rate; and we have just seen how food-supply has been the dominant factor in the Great War, controlling the amount of energy the belligerents had at their disposal—i.e., the amount of work they could do. But the importance of the work itself has hardly been fully appreciated; the importance upon the health of the community of modern industrial life; even though Sir JAMES PAGET laid it down that "fatigue (too much work) has a larger share in the promotion or permission of disease than any other causal condition you can name." Fewer hours of work should mean less fatigue; and the health of the nation is bound to react, though several years must elapse before the reaction can be measured. Health has reacted to the social changes brought about by the sudden advance in civilisation of the last 200 years, and

more particularly of the last 80 years, which has resulted from industrial development guided by intellectual progress. The food-supply has increased and the population has increased, as MALTHUS said it should. Vital statistics indicate a diminution in our exposure to, and an increase in our capacity for resisting, the onset of disease; and in no case has this been more manifest than in the decline in mortality from tuberculosis. What reaction will follow the present movement which should eliminate much industrial fatigue?

Dr. VERNON traced the present possibilities of the six-hour day, and showed by instances taken from the iron and steel industry, and the tinplate industry, that the rate of output per worker cannot always be increased in proportion to the reduced hours. He chiefly dealt with the economic question of output, which is fundamental in the industrial world; for industry must obtain a surplus of output; that is, a greater output per working unit than that unit's requirements necessitate, if the social circulation which supplies him with materials, and absorbs his output, is to be maintained. Hours of labour and conditions of work have to be arranged to ensure this surplus of output which is wealth, the blood-stream of industry. ÆSOP'S fable of the limbs and the stomach is still a useful parable; the stomach must be fed for nourishment to reach the limbs. The constitution of the State has in the past been showing signs of greediness and of an overloading of its metaphorical stomach; dyspeptic symptoms have followed—nightmares of unrest; and somewhat unwieldy corporations have developed, while the work-a-day limbs have suffered from unequal distribution of nourishment. But if the hands go on strike and refuse to feed the stomach, they in their turn can receive no nourishment and must starve. Recently a tendency for more equal distribution has manifested itself, but for this to be maintained output must be maintained, and not only maintained but increased. Can this be effected by adopting the six-hour day? Dr. VERNON'S data show that so far as certain dexterous processes are concerned the answer is "Yes," but that in regard to the majority of automatic processes the answer is a definite "No." Modern industry has developed on a longer-day basis and has not yet organised itself to meet the requirements of an eight-hour day, even though this modification has for years been demanded by the workers. If ever the six-hour day proposed by Lord LEVERHULME is to be generally adapted—and from the point of view of health and welfare it has much in its favour—industry must have due notice. Labour-saving devices must be invented, and processes brought more under the control of the workers' own dexterity.

These things can probably be done, but not in a moment, and to-day each process must be considered on its merits. We must encourage in every way a reduction of hours by permitting multiple short shifts, which to-day are discouraged, if not rendered impossible, for protected labour by the inelastic provisions of the Factory Acts. If short shifts prove an economic success, which can only result through energetic action on the part of employers, and more especially of the workers, then industry will adopt them without compulsion, and will organise itself so that they can be introduced where to-day they could only prove an economic failure. Legal action at present should be limited to fixing some maximum period

for employment, say eight hours a day, or, better, a 48-hour week, and should leave to industry every possible latitude to work out its own salvation within this limit. The step would be a great advance, for it must be remembered there is no legal limit to-day (except for miners) to the hours of adult male labour. At some future time, in the light of experience gained, a further reduction of the maximum might be found of value to the health and wealth of the State; but in the light of present knowledge with industry organised as it is to-day there are at least three dangers in adopting a universal six-hour day: (1) health might be impaired by too little activity, for work is even more necessary to health than rest; (2) the unoccupied time might be spent unprofitably and harmfully, since the working-class population have not been accustomed to having leisure hours to devote to mental and physical recreation; and (3) surplus of output might not be obtained, when economic circulation would cease.

### Marking Time in Psychiatry.

IN common with other Government departments, the Board of Control has been seriously hampered in its activities by the conditions obtaining during the war, which not only depleted its staff but also thrust upon it a number of emergency duties of a difficult and responsible character, notably in connexion with the adaptation for use as war hospitals of certain asylums under its supervision. The present report, though it appears several months after the termination of hostilities, inevitably bears traces of this preceding period of stress, and can hardly be expected, therefore, to come quite up to the standard of fullness and accuracy which may reasonably be looked for in normal times in the reports of a State authority responsible for such important duties in regard to the care and treatment of the insane. Even, however, when full allowance has been made for the difficulties of the moment, it cannot be said that the inadequacy of the Board's last report is entirely accounted for. In the first place, the statistical information which the report contains is very defective, even for a war-time publication, and it is badly arranged; there are no details as to the age distribution of patients on first admission and on recovery; there is only one meagre table showing the percentage distribution of deaths from certain causes at three different age-periods, which, in the absence of any figures indicating the age distribution of the whole asylum population, is quite useless; no particulars are given as to the assigned causation of insanity or as to the clinical forms of disease in patients admitted to care. If the omission of any reference to these latter points could be explained by scepticism on the part of the Commissioners regarding the value, in the present state of knowledge, of any attempt to classify the forms of mental disease or to distinguish their ætiological factors, it would perhaps be a comprehensible position; but in point of fact the Board has had in use for many years past a most minute and complex table of classification with an equally complex table of alleged causes of insanity, and the statistical information collected every year from all the asylums in the country has to be furnished in accordance with these schedules. If

this system is too elaborate and too artificial to be of any use in practice, as may well be the case, and if it is not possible to substitute for it some provisional scheme of a simpler and less ambitious character, it should, at least, be feasible to show the statistical movement of a number of the generally recognised clinical groups of mental disease, as, for instance, general paralysis, the insanity associated with epilepsy, and the insanities of child-birth. Meanwhile the lack of information of this sort renders it the more necessary to provide statistics regarding such matters as the age at onset of attack and the age distribution of the asylum population. If space is a consideration, it would be easy to find room for the inclusion of these really important data by omitting details about trivial administrative points, such as the extension of a certificate to allow an institution to increase its accommodation by one bed, or the purchase of  $3\frac{1}{2}$  acres by a county asylum. Such matters, if worth recording at all, might well be relegated to an appendix; they are quite out of place in the text of the report. It is desirable to make these criticisms at the outset, because the absence of adequate statistical data imports a large element of uncertainty into the interpretation of the two main facts disclosed in the report—viz., the high death-rate amongst asylum inmates and the increase in the number of admissions to asylum care during 1918.

On Jan. 1st, 1919, the number of notified insane persons under care in England and Wales was 116,703—49,936 males and 66,767 females—showing a decrease of 9138 as compared with the number under care on the corresponding date in 1918, and a decrease of 23,763 since the beginning of the war. The number of patients placed under care last year was 21,765—10,078 men and 11,687 women. Of this number, 8835 men and 9726 women had not previously been under asylum treatment. The admissions for the year show an increase in both sexes as compared with the figures for 1917, and the number of first admissions of women is higher than any previously recorded. It should be noted that the figures do not include 3000 to 4000 patients under observation in military hospitals, many of whom will ultimately be certified. During the year 5907 patients were discharged recovered, being a percentage of recoveries to admissions of 27.14—the lowest on record. The decrease in notification has been due in the main to the abnormally high death-rate, which, calculated on the daily average number of patients, amounted last year to 19.56 per cent., as compared with 16.86 per cent. in 1917 and with 9.43 in the pre-war year 1913. This excessive mortality was the subject of a special inquiry by a committee of the Board, who reported that its main cause was the reduction in quantity and deterioration in quality of the food supplied to patients. The unpleasant impression which this statement makes will not be lessened when it is observed, from Statistical Table VI. in Part II., that the increase in the death-rate was confined to institutions receiving paupers, and did not affect the registered hospitals which deal only with private patients. Further information on this matter is clearly desirable, especially as to whether the rationing of asylum patients was scientifically adjusted to their needs as sick people. The Commissioners, as a result of their investigations, judged it necessary to make a series of suggestions to the asylum authorities, and it is

<sup>1</sup> Report of the Board of Control (Lunacy and Mental Deficiency) for 1918.

a little surprising to find that their first recommendation is to the effect "that patients should be weighed at least quarterly and a record kept." Is it to be inferred from this that there are institutions for the insane where patients are not periodically weighed, and that it is only after a disastrous experience of excessive rationing that the utility of such weighing is discovered? The other recommendations of the Commissioners refer mainly to precautions against the spread of communicable diseases, especially tuberculosis and dysentery, which became much more prevalent in the asylum population during the war. The measures advised are generally sound and practical, but the Board of Control can hardly be called progressive scientifically. The financial statistics reveal the interesting and illuminating fact that in the year ending March 31st, 1918, the expenditure on county and borough asylums for the insane amounted to considerably over £4,000,000, and the expenditure for scientific research in connexion with mental disease was £375.

It will be seen that the report does not give a very encouraging view of the present position of insanity in this country, and that it is likely to strengthen the growing sense of dissatisfaction with our existing methods of dealing with the insane. The very tone of the report, with its constant insistence on the purely custodial and administrative side of asylum work, points to what is amiss: it is the failure to recognise, in practice as well as in profession, that insanity is a disease which must be studied and treated in the spirit and by the methods of medical science. The reforms which the Commissioners themselves advocate, such as the establishment of clinics for mental disease in connexion with general hospitals and the amendment of the law to allow of the treatment of cases of insanity in the incipient and more curable stages, will, it may be hoped, do something to remedy the defects of the present system, but it is evident that more radical changes will be needed if psychiatry is to be freed from the influences which now impede its progress, and is to be brought into contact with the main current of medical thought and practice.

## Annotations.

"Ne quid nīms."

### IRISH PUBLIC HEALTH COUNCIL.

THE Chief Secretary for Ireland, acting under Section 10 of the Ministry of Health Act, 1919, has nominated the following to be the medical members of the Irish Public Health Council:—Dr. E. Coey Bigger, now Medical Commissioner to the Local Government Board for Ireland, to be chairman of the Council; Sir John W. Moore, president of the Royal Academy of Medicine of Ireland and chairman of the Public Health Committee of the General Medical Council; Dr. Robert J. Rowlette, nominated by the Irish Medical Committee and the Irish Medical Association; Dr. Alice Barry, medical superintendent of the Child Welfare Work Branch of the Women's National Health Association, nominated by the Irish Medical Committee. The non-medical nominated members of the Council are: Countess of Kenmare, chairman of the Advisory Council for Ireland of the Queen Victoria Jubilee Institute; Mrs. J. McMordie, member of the Tuberculosis Committee of the Belfast Corporation, and of the Belfast Insurance

Committee; Sir James M. Gallagher, ex-Lord Mayor of Dublin and ex-chairman of the Dublin Joint Hospital Board; Mr. J. Ewing Johnston, M.R.C.V.S., president of the North of Ireland Veterinary Medical Association; Rev. P. Kerlin, C.C., nominated by the (Irish) National Association of Insurance Committees; and Mr. John Drennan, representing the approved insurance societies. It will be remembered that the Vice-President and two other Commissioners of the Local Government Board for Ireland; the chairman and two other Irish Insurance Commissioners; the Registrar-General of Births, Deaths, and Marriages in Ireland, are ex-officio members of the Council. Major George A. Harris, of the Local Government Board for Ireland, has been appointed secretary to the Council, the offices of which will be at 33, St. Stephen's Green, North Dublin. The first meeting of the new Council will be held on Thursday, Oct. 2nd.

### THE RODENT MENACE.

CIVILISATION is daily teaching us that we are members one of another, and this applies especially to our failings and failures, and even to our diseases, for one carries the germ and another catches it. On the animal kingdom we are still more intimately dependent, for they frequently act as hosts to our infections during inhospitable intervals. What should we know of malaria if it was not for the mediation of the mosquito, or of plague if it was not for the rat? And the rat is becoming ever more and more suspect. In regard to protozoal parasites it has been long known to harbour the *Trypanosoma lewisi*, an apparently harmless guest. The Japanese have shown the rat to be the host of two other protozoa which, while harmless to itself, are capable of causing serious illness in man. These are the *Spirochæta icterohæmorrhagiae* Inada and the *Sp. morsus muris* Futaki. The work of Inada, Ido, Hoki, Kaneko, and Ito, on the first-named has since been confirmed by the demonstration of rat carriers in France, Belgium, Algeria, and the United States of America. In England the presence of the specific spirochæte of hæmorrhagic jaundice in the rat was not fully proved until the investigation of Major A. G. R. Foulerton, carried out in the Hygiene Department of University College, London, and recently printed at the instance of the Public Health Department of the Corporation of London. Major Foulerton examined 101 rats caught within the City and Metropolitan area, and in 4 of them found a spirochæte which killed a guinea-pig on the twelfth day with all the characteristic appearances of spirochætal jaundice. Three of these rats were from a batch of 12 caught at a general store in the City last November; the fourth from a batch of 7 from another part of London. Dr. A. C. Coles stated in our columns<sup>1</sup> last year that he had found spirochætes resembling the *Sp. icterohæmorrhagiae* in 9 out of 100 rats caught in the neighbourhood of Bournemouth, and gave excellent micro-photographs of the protozoa, but he did not proceed to confirm his results by animal inoculation. Major Foulerton discusses the method of transmission of the protozoon from rat to rat and rat to man, inclining in the first case to accidental inoculation, in the latter to the infection of food and drinking water. For the present the rat-flea has nothing to say to this matter.

In a presidential address, delivered last year before the Royal Society of New South Wales and

<sup>1</sup> THE LANCET, 1918, i., 468.

since reprinted and circulated, Dr. J. Burton Cleland pointed out that a town that lets its rats multiply is exposed to a menace that may lead to enormous financial losses and possibly a heavy death roll. Rats live a communal life in direct contact with each other, and thus the passage of any pathogenic organism is facilitated, while in the passage the pathogenicity of the less lethal forms is probably increased. He went on to discuss rat leprosy, which is widely distributed, though of relatively rare occurrence, its incidence among the rat population in New South Wales being much about the same as the incidence of leprosy amongst the human population. From investigations on its occurrence in rats it might be inferred that there is one diseased rat in Sydney for every 100,000 examined, whilst in New South Wales there is approximately one leper to 80,000 inhabitants. The question arises as to whether there is any possible connexion between the two diseases, whether, indeed, they are not due to the same organism. Dr. Cleland sketches the phylogenetic history of the tubercle bacillus, showing that it was originally a saprophyte, as, for instance, the acid-fast timothy-grass bacillus is still; the next stage being its accidental introduction by the alimentary canal or through wounds into the tissues of vertebrates, where it has found itself capable of living and multiplying, even though in such an unusual environment; finally, being given frequent opportunities of escape from its host through ulceration of the lungs and of introduction consequently to fresh individuals, its pathogenicity has been increased and its saprophytic qualities have been diminished or lost. The rat leprosy bacillus may, he suggests, be in somewhat the same transition stage.

These are new aspects of the rodent menace about which sufficient is known to demand the more active measures of suppression in this country. The Rats Orders of 1918 and 1919 gave local authorities the liberty to organise local campaigns. Several county councils have appointed official rat-catchers. In Leicestershire a summer campaign resulted in the death of 125,223 rats, for which a sum of £1525 was paid out. The Board of Agriculture has, in harmony with a growing habit, suggested a "rat week" for Oct. 20th-27th, in which village communities should compete one against the other in baiting, trapping, and ferreting. All this is to the good, but we doubt the attainment of the end in view so long as slack authorities are not gently urged by legislative action; for rats harried on one side of a boundary can take refuge on the other side where the human community is more lenient. We regret that Lord Aberconway's Rat Destruction Bill did not become law. It is for the Ministry of Health to devise appropriate legislative action which shall not be held up by lack of time or interest in the Chamber.

#### THE MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held in the board-room of the Public Medical Service at Leicester, under the presidency of Sir John Tweedy, when the report presented began by recording the great loss to the Union incurred by the death in April last of the general secretary, Dr. A. G. Bateman. Dr. Bateman's services were largely instrumental in safeguarding the rights, liberties, privileges, duties, and ethical obligations of medical men in their relations with each other and with the public, and the appoint-

ment of his successor, Dr. James Neal, with a long experience behind him as deputy medical secretary of the British Medical Association, promises a continuation of Dr. Bateman's activities. During the year 123 cases were referred to the Union's solicitor, Mr. W. E. Hempson, 24 being libel and slander actions, prosecuted or defended; 15 malapraxis actions, defended; 8 prosecutions of unqualified persons; 76 arbitration and personal matters. The out-of-pocket expenses for litigation amounted to £278, and the total law charges to £1136. No action conducted by the Union has been lost during the last two years. The profit and loss account for the year shows a credit balance of £2016 at the beginning and £2830 at the end of the year. The most interesting feature of the report is the record of a difference of opinion which has arisen between the Union and the General Medical Council in regard to requests addressed by the Council's acting registrar to members of the Union inquiring their reasons for refusing medical attendance in certain cases in regard to which complaint had been received by the Council. The reply of the Penal Cases Committee of the Council, justifying the Council's action, is given at length in the report. The Union takes the view that a continuance of this new procedure can only lead to a conflict between the General Medical Council and registered medical practitioners. The number of members on the register of the Union is now 8719.

#### THE POSOLOGY OF EMETINE.

At a recent discussion<sup>1</sup> on the posology of emetine at the Société de Thérapie, Paris, Dr. Chauffard stated that he preferred giving subcutaneous injections of the drug as being less painful than intramuscular. He never used rectal injections, as they were liable to cause a recrudescence of dysentery. In moderately severe cases of amœbic dysentery he gave two injections daily of 3-5 cg. of emetine hydrochloride. The patient received a series of injections for from six to eight days, followed by a week to a fortnight's rest. The injections were then resumed if necessary. Dr. Dopfer stated that injections of emetine might give rise to toxic symptoms, such as cardiac, digestive, and nervous disturbance, which was sometimes fatal. The toxicity of emetine was favoured by its accumulation in the system and by its slight degree of daily elimination. In practice, therefore, it was advisable not to exceed a total dose of 1 g., the daily dose being 8-10 cg. If toxic symptoms developed before the total dose of 1 g. was reached, treatment should be suspended. If several courses of emetine treatment were required for relapses of amœbiasis, before undertaking a second series it would be necessary to wait for complete elimination of the drug from the first course—i.e., 40 to 60 days. Major F. Noc advocated the following treatment of amœbic dysentery: (1) an injection of emetine in doses of 4 cg. daily for four days; (2) an intravenous injection of 0.30 g. neosalvarsan on the first or second day; (3) milk as a drink throughout the duration of treatment; (4) small doses of extract of ipecacuanha (5 or 10 cg.), in pills, three times a week; (5) one or two injections of emetine every week or fortnight, according to the frequency of relapses and the number of cysts in the stools; (6) reinjection of small doses of neosalvarsan (0.30 g.) at fairly long intervals concurrently with the injections of emetine.

## THE IDEAL ATMOSPHERE.

THE chemistry of the air was established with some degree of certainty a good many years ago. The essential constituent, of course, for the maintenance of animal life is oxygen absorbed in the process of respiration and passed on to the tissues by way of the circulatory system. These are elementary facts. The physics of the air has only comparatively recently received promising study. It is well to remember that the chemistry of the air does not vary, while the physics of the air does considerably in ways which affect the well-being of the individual. As is well known, the great and important organ, the skin, is susceptible to the fluctuations in the physical conditions of the atmosphere. Terms such as stuffy, oppressive, heavy, thundery, fresh, bracing, are constantly used as expressing certain varying conditions of the air we continually experience, but all through these phases its chemical constitution remains the same. We may disregard the chemistry of the air, as that is assured to us as a constant in all ordinary circumstances—we are taking no regard, of course, of added impurity. The physics of the air, on the contrary, is an ever-varying factor which determines its adaptability to the physiological convenience of the individual. The progressive studies of the physical conditions of the air are rapidly modifying our views on questions of indoor warming and ventilation: these refer to the correct estimate of a healthy aerial environment independently of chemical purity or composition.

In this connexion it is interesting to recall that as far back as 1892 a Report of THE LANCET Sanitary Commission on the Ventilation of Theatres and Places of Public Assembly was published in our columns. This report referred mainly to the steps that were being taken in regard to the ventilation of the great amphitheatre of the Paris Sorbonne. The task was entrusted to an eminent architect and hygienist, M. Emile Trélat, who had already consummated a scheme at the Vienna Opera House which had given great satisfaction. This scheme took for its ideal of well-being in regard to indoor ventilation the conditions prevailing on a fine autumnal day when the air is cold and crisp, but when the rays of the sun are still warm. M. Trélat maintained that the colder the air the greater the internal oxidation in breathing, and therefore the greater the internal warmth. According to these views if, while breathing cold air, the body can be preserved from external cold by the radiation of heat from the sun or other sources, there follows the most healthy and the most enjoyable state of physical existence. These views receive confirmation to-day, for practically the same conclusion has been reached by Dr. Leonard Hill in his admirable series of researches on the subject. In his recent report on "The Science of Ventilation and Open Air Treatment" to the Medical Research Committee (Special Report Series, No. 32, published by His Majesty's Stationery Office), he repeats his statement that the ideal method of warming and ventilating rooms would give radiant heat, a warm floor, and agreeable movement of cool air—the conditions, he adds, of a sunny spring day out-of-doors. Except that M. Trélat speaks of a fine autumnal day, whereas Dr. Hill speaks of a sunny spring day, these investigators appear to have arrived at the same ideals. The weather of these islands does not always approach

these ideals, but the suggestion plainly is that the favourable conditions described should be imitated as nearly as possible in regard to indoor heating and ventilation. The appeal to scientific instruments for guidance in these matters has hitherto been of little value, and particularly does this apply to the ordinary thermometer, for, as Dr. Hill rightly observes, the healthy aerial environment is not a question of actual temperature, but (1) of the cooling power of the air, that depending not only on the temperature, but far more on the movement of the air; (2) the radiant energy of the sun or other source received by the skin; and (3) the drying power, depending upon humidity, movement of the air, and radiant energy received, which affects the cutaneous nerve-endings by varying the difference between the temperature of the surface and the blood temperature in the deeper layers of the skin.

Towards determining the physics of the air, particularly in regard to its cooling and evaporative power, the kata-thermometer has been devised by Dr. Hill. This is an alcohol thermometer designed primarily for the measurement of its own rate of cooling, when its temperature approximates to that of the human body. The classic wet- and dry-bulb thermometer is thus superseded where measurements in behalf of the human body are concerned, and the records given by the dry and wet kata-thermometers form a well-begun means of differentiation as to what is and what is not a healthy aerial environment. In his observations in our last issue on the hot season in Mesopotamia, Dr. F. E. Fremantle dwelt on the value of the kata-thermometer in determining the conditions under which the white man can continue to exist in tropical climes. Scientific measurements of this kind are interesting, though their lessons sometimes seem late in supporting long-established convictions. Cool, clear air has for long been accepted as most congenial to healthy respiration, but the comfort of the body needs to be sustained by artificial warmth in chilly times. The individual who shivers is miserable, and his suffering may well denote the beginning of disturbance of health.

## A PROGRESSIVE MOVE.

IN the advertisement pages of this week's issue of THE LANCET appears a notice indicating an interesting departure by the authorities of the Hospital for Nervous Diseases, Maida-vale. The advertisement invites applications for the post of psychologist to the hospital, from which we assume the hospital is about to establish the nucleus of what should develop into a psychological department. From the report of the medical registrar of the hospital for the last year it appears that there is much material awaiting investigation, for of the 4000 patients treated at the hospital in 1918 nearly half are classified as suffering from functional nervous disorders. Apart from the treatment of these patients and the opportunity for original work, much can be done for many of the patients who are classified as suffering from organic nervous disease, but who also show faulty mental adjustment, and the appointment of a psychologist displays the intention to place the facilities of the hospital at the disposal of those competent to carry out original investigation in psychotherapy.

## TUBERCULOUS INFECTION IN SCHOOL CHILDREN.

Dr. Alexander Arnfinssen<sup>1</sup> has tested 80 school children between 6 and 18 years of age at Trondhjem, in Norway, with von Pirquet's reaction, and found that it was positive in only 37·8 per cent. Although Trondhjem is an old city, tuberculosis until comparatively recently was almost unknown there. The surrounding country, from which the city partly draws its population, had been relatively protected from infection up to 1850, when the construction of railways and good highroads brought about a change in the situation. In spite of the low percentage of the tuberculin test, the mortality from tuberculosis is higher at Trondhjem than in other Norwegian cities. The writer, therefore, suggests that the greater the dissemination of tuberculous infection the lower is the mortality from the disease owing to the population having acquired a relative immunity. The state of nutrition of the children is very good, probably owing to the fact that 82 per cent. had been breast-fed up to the age of 3 months or more. Children from tuberculous homes showed a positive cuti-reaction in 68 and 64 per cent. for boys and girls respectively.

## PERFORATION OF THE LUNG A SEQUEL OF PERFORATION OF THE STOMACH.

In the *American Journal of the Medical Sciences* for August Dr. J. Friedenwald has reported a very rare sequel of gastric perforation—subphrenic abscess perforating through the lung. A man, aged 51 years, was seen in consultation. He complained of gastric symptoms for 35 years, mainly fullness after meals and belching. For the past eight or ten years there were periodic attacks lasting three or four weeks to several months, characterised by pain in the stomach appearing two hours after meals, and relieved by soda and rest. Pyrosis and hunger pain frequently occurred. He vomited at times, but there was no history of hæmatemesis or melæna. After an attack lasting some weeks he was seized with agonising pain in the upper abdomen requiring injections of morphine. The abdomen was distended and there was a tender epigastric area. Next day there was dull pain in the left kidney region which radiated towards the epigastrium. The pain lasted ten days, and was accompanied by a temperature ranging from 101° to 103° F. Cough and hiccough developed and purulent expectoration followed. During the first day he expectorated about a quart of pus. When the expectoration began the temperature and pain diminished. He was admitted to hospital. On examination he was thin and pale. The tongue was coated, and there was marked pyorrhœa alveolaris. In the chest only some impairment of the percussion note in the region of the right scapula could be detected. Auscultation was negative. The abdomen was somewhat distended, and the recti were spastic. There was a tender area in the epigastrium and left lumbar region, over which was a burn caused by hot applications. The liver extended a finger-breadth below the costal margin. X ray examination showed a high stomach with rapid expulsion and defect at the pyloro-duodenal junction (revealing an ulcer), dilatation of the bronchi, and cloudy infiltration below the right clavicle. The temperature was 100°.

On the first day in hospital he expectorated about a pint of pus. The expectoration rapidly diminished and ceased in a week. The pus was creamy and of a putrid odour. It contained colon bacilli and streptococci in abundance. Recovery quickly took place. Evidently the attack of abdominal pain indicated gastric perforation, which was followed by subphrenic abscess, and finally by perforation of the lung. The complete evacuation of the abscess led to recovery. In gastric perforation producing subphrenic abscess the pus usually accumulates rapidly and the symptoms are very acute. There is often sudden severe pain in the epigastrium or hypochondrium radiating to the shoulders with dyspnoea due to pressure on the diaphragm. There are usually vomiting, hiccough and weakness, and acceleration of the pulse. Fever, with chills and sweating, is not uncommon. Dr. Friedenwald could find recorded only four cases—all German—in which perforation of a gastric ulcer was followed by rupture through the lung.

## INTELLIGENCE TESTS.

It was announced some months ago that the authorities of Columbia College, New York, had resolved to replace their matriculation examination from July last by a series of psychological tests for the selection of those candidates for admission who could profit most by a University course of study. For many years past the utility of special mental tests has been gaining increasing recognition. Their value was finally established during the war, and nowhere so conclusively as in the United States Army, in which they were applied to about one and a half million recruits. A brief report of the methods adopted for measuring intelligence by these Army mental tests has now been issued from the Government Press, Washington, showing also some of the results obtained and the practical applications secured. Men of too low-grade intelligence were rejected, while those of superior intelligence were considered for advancement, the most suitable being selected for special training or for specific Army duties. On the basis of these tests endeavours were made to provide each unit (save in certain arms of the Service) with its proportion of superior, average, and inferior men, instead of leaving the proportion to chance. In this way were formed units of uniform mental strength which could be trained at a uniform rate. Intelligence, of course, is only one of the factors in military efficiency, but it is probably the most important single factor. The results obtained from intelligence tests and from other mental tests by the United States Army and by our own Admiralty during the war are clear indications of their future value in the work of human selection and vocational guidance.

## ANTHROPOLOGY AS AN IMPERIAL STUDY.

THE Mackie Anthropological Expedition to Uganda, postponed for obvious reasons on the outbreak of the war, is now to get to work. Under the direction of the Royal Society, the mission will be in the personal charge of the Rev. John Roscoe, whose thorough acquaintance with the subject and long residence in Uganda as a missionary, constitute exceptional qualifications. The original idea was that the Colonial Office should finance the scheme, but Mr. Lewis Harcourt, upon full consideration, did not concur. Accordingly, Mr. P. Jeffrey Mackie, of

<sup>1</sup> Norsk Magazin for Lægevidenskaben, 1919, lxxx., 508-530.

Glenreadell, a well-known Scotch distiller, was approached and he undertook to defray the entire cost. We hope that the results of his generosity will provide a valuable contribution to our knowledge upon a subject hitherto unduly neglected. Anthropological study is of particular importance to the British Empire, to which has fallen the charge of so great and various a collection of the human race. The expedition could not be in better hands than those of Mr. Roscoe, lecturer to the University of Cambridge in African Anthropology, and author of an authoritative work on the folklore of the Baganda.

#### THE OPENING OF THE WINTER SESSION.

A WELCOME sign of the return to more normal conditions of life is the renewed foregathering of past and present members of London medical schools at the commencement of the winter session. The social dinners which one by one have been dropped during the war are again to take place, and will bring together for the first time men and women whose medical duties have taken them to the ends of the earth, and given them, in a brief year, more than the normal experience of a life-time. Some of the London schools of medicine are, as usual, giving their newcomers the opportunity of hearing the stimulating experience of veterans in the profession.

Dr. Wilfrid Ombler Meek died with tragic suddenness on Sept. 14th at the Brompton Hospital Sanatorium, Frimley, where he had long been resident medical officer. He was in his fortieth year.

THE inaugural sessional address at the Pharmaceutical Society of Great Britain will be given on Wednesday, Oct. 1st, at 3 P.M., by Mr. W. J. Uglov Woolcock, M.P., at the School of Pharmacy, 17, Bloomsbury-square, London, W.C.

UNIVERSITY OF LONDON: LECTURES IN ADVANCED PHYSIOLOGY, 1919-1920.—The following are recognised as advanced lectures which a candidate at the B.Sc. Honours examination may name for part of his examination. *King's College*, 1st term:—Dr. Da Fano: Histology of the Nervous System. Ten lectures at 4.30 P.M. on Tuesdays, beginning Oct. 17th. *King's College for Women*, 3rd term:—Dr. E. Mellanby: Nutrition. Eight lectures at 5 P.M. on Mondays and Wednesdays. *St. Bartholomew's Hospital*, 2nd term:—Mr. J. W. Trevan: The Reaction of the Blood and Acidosis. Eight lectures at 4.30 P.M., on Wednesdays. *Guy's Hospital*, 2nd term:—Dr. M. S. Pembrey and Dr. J. H. Rytffel: The Regulation of Respiration. Eight lectures at 4.30 P.M. on Thursdays. The precise dates of delivery will be announced later, as will also the place of delivery of the following: 2nd term:—Mr. W. L. Symes: Physiologically Balanced Solutions. Eight lectures at 5 P.M. on Tuesdays. 3rd term:—Mr. J. A. Gardner: The Bio-chemistry of Sterols. Eight lectures at 5 P.M. on Tuesdays. At the Imperial College of Science and Technology during the 1st term Professor A. D. Waller will deal with the Energy Balance of the Human Body and Electrical Signs of Motive Phenomena at 5 P.M. on Wednesdays, beginning on Oct. 15th, but these lectures do not count for examination. Intercollegiate courses also approved for the Honours B.Sc. examination will be delivered at University College during the 1st term by Professor Bayliss on Physical Chemistry in Relation to Physiology; and during the 3rd term, at King's College, by Professor Halliburton and Dr. Rosenheim, on Advanced Chemical Physiology; at Bedford College, on Advanced Practical Histology; at St. Bartholomew's Hospital, by Professor F. A. Bainbridge, on Electrical Changes on Skeletal and Cardiac Muscle (practical work); and during the 2nd term at Guy's Hospital, on Practical Work on Respiration. Further information may be obtained from the heads of the laboratories in which the lectures are given, and in the case of courses by Professor Waller, Mr. Gardner, and Mr. Symes, from Professor Waller, Physiological Laboratory, University of London, South Kensington, S.W.7.

## THE INDUSTRIAL EMPLOYMENT OF MOTHERS:

### FRENCH AND GERMAN EXPERIENCES.

AN account has been given of the steps which were taken during the war for protecting the welfare of the children of women employed in factories in France and Germany in a report which was issued a short time ago, and which was prepared in the Intelligence Department of the Local Government Board. The infant welfare work which has been done in these countries is suggestive. A short description of it may be useful so as to enable a comparison to be made with similar work in England.

#### France.

In France, as in this country, women were extensively employed in factories and on munition work, and attention was aroused to the dangers of such employment for the health of the mothers and infants. Statistics compiled from the weekly bulletins of municipal statistics for Paris showed that during the second year of the war, as compared with the first, there was an increase in the percentage of stillbirths and cases of maternal mortality, and in the number of abandoned infants. The number of premature births had also increased. There was a vigorous discussion on the subject in the Academy of Medicine in December, 1916, as an outcome of which a committee was appointed to consider the matter. The resolutions which were passed were strongly supported by the Ministry of Labour, the Ministry of the Interior, and the Ministry of Munitions. The need was emphasised for the compulsory establishment, in every war factory where women were employed, of a nursing room furnished with cradles and reserved exclusively for breast-fed infants. It was held that the mothers should be allowed to attend to their infants during working hours without any loss of wages. They should be employed on day shifts only. There should be, in addition, a crèche for artificially-fed infants and a day nursery for children up to 4 years of age attached to each factory, or to a group of factories, and in factories where a number of women were employed a welfare supervisor should be appointed, whose duties and functions should be similar to those of welfare workers in English factories.

The vital need for breast-feeding was so well recognised that in August, 1917, a law was passed under which certain amendments were made in and clauses added to the second book of the Industrial Code. These clauses provided that two periods of 30 minutes each were to be allowed during working hours, and in addition to the usual rest-periods, to nursing mothers to breast-feed their infants up to 1 year of age, and they were to be allowed to attend to their infants on the premises. Whether this law was complied with was a debated point. M. Pinard reported to the Academy of Medicine that the effect was nil and that the measures for the protection of expectant mothers existed only "on paper."

The need for crèches and day nurseries for the children of women workers was also recognised. In 1897 the crèche was legally defined as "an establishment for the hygienic and moral care of infants until they have reached their third year." Crèches might be opened only on the authorisation of the prefect, and were to be subject to inspection by persons appointed for the purpose, either by the Minister of the Interior or by the prefect. A report on the working of the crèche, and a medical report, had to be submitted to the prefect each year, and he had power to order a crèche to be closed if he considered the arrangements defective. Later in the same year it was made obligatory for every crèche to be supervised by a doctor; and no infant could be received at a crèche without a medical certificate showing that it was free from infectious disease. During the war the crèches in France have had to contend with many difficulties and anxieties, among which were scarcity of milk, high price of food and coal, lack of funds, difficulties in arranging for medical supervision owing to the mobilisation of so many of the doctors, and difficulties in finding a working staff which was adequate in number and competence. In various industrial regions, however, crèches were established in connexion with a factory or group of factories, to a very large extent by the employers themselves. Among those specially mentioned in the report are Messrs. Schneider at

Creusot, the Châtillon-Commentry Works at Montluçon, the "Comité des Forges"—a federation of nearly 60 employers' associations representative of the metal, electrical, mechanical construction, railway material, and other industries—and other employers in Basse Indre, Saint Etienne, in the india-rubber industry of Auvergne, Clermont, Thiers, and the neighbouring district. A group of firms formed an association at Levallois Perret and Neuilly, and erected a model building, the cost of the building being met by the employers themselves. Similar measures were carried out elsewhere. The manner in which the employers have organised and assisted in providing these institutions is remarkable.

The creches receive grants from the State, Department, or Municipality, from two, or even from all three; some, however, receive no grant from public funds. In many creches a small charge is made to the mothers for each child cared for, more as a matter of principle than for the money obtained. Children of 2 years of age can be sent to infant schools or cared for in day nurseries (garderies). A day nursery becomes an infant school if any instruction is given, and is subject to inspection by the education authority, and becomes a creche if children under 2 years are admitted.

The French working woman appears to be more prejudiced than her English sister where creches and similar institutions are concerned, preferring, in many cases, to leave her children with foster-mothers. Some think the infants would thus be better cared for, others regard it as more respectable to leave their children with neighbours than take them to a free creche.

French women have long been accustomed, as a rule, to send their children to be cared for in country villages by foster mothers, often arranging for them to be breast-fed. The mortality among these children was at one time extremely high, and for their protection in 1874 the "Loi Roussel" was passed, which, among other provisions, stipulated that a record should be kept of all facts connected with the boarding-out of infants, and that the children should be examined medically from time to time. It was realised, however, that the protection afforded by this law was not sufficient, and infant welfare consultations were set up in a number of Departments to which foster-mothers were encouraged to bring children under their care for medical supervision, advice, and help. In the Department of Seine et Oise there were in 1914 nearly 100 consultations. In 1917 a report for this department stated that of 4893 infants attending only 192 died before reaching 1 year of age—a mortality rate of 39 per 1000, the general infant mortality rate for the department in 1916 being 67 per 1000, as compared with 73 per 1000 in 1913. In estimating the value of these consultations it should be realised that, where attendance is voluntary, the best mothers and foster-mothers attend in greater numbers than others, and among their children, or the children in their care, the infant mortality-rate would naturally be lower than the general infant mortality-rate of the Department.

#### *Germany.*

The infants of mothers working in factories in Germany have usually been cared for in creches or infants' homes and the children below school age in day nurseries, whilst for children of school age "day shelters" were provided where they could spend their free time until their mothers returned from work. During the war the number of creches and day nurseries greatly increased. Many were carried on by municipal authorities, and creche associations and other organised bodies made considerable efforts to extend the existing accommodation and open new creches. In many cases it was found necessary to open the creches earlier and close them later, and often to keep them open all night. Among the many difficulties experienced were the scarcity of food, soaps, and rubber teats. At the end of 1916 the "Central Office for Women's Employment" was set up within the War Bureau and placed under the direction of an experienced medical woman. Amongst the duties attached to the office was that of suggesting and carrying out measures for the protection and well-being of the women, and of seeing that the children did not suffer on account of the employment of their mothers.

The large associations interested in welfare work among women and children were appealed to, and in January, 1917, was formed the "National Committee for Women's War

Work," which, together with the "Central Office for Women's Employment" and various local committees, was responsible for much of the welfare work which was carried out during the war. In Germany the general feeling appeared to be in favour of boarding-out the children in suitable foster homes rather than of placing them in institutions. The creches, day nurseries, and day shelters received financial support from (1) private contributions; (2) payments by mothers; (3) municipal grants (many creches being supported entirely by municipalities, who in their turn received Imperial and State aid); (4) Imperial funds (half to two-thirds of any expenditure on war relief); (5) State aid; (6) State insurance institutions, &c. (fire insurance societies have contributed on the ground that children left at home without supervision are frequently the cause of fires); and (7) contributions from employers. Under the Imperial Industrial Law women workers in factories were forbidden to work on night shifts, their working day was limited to ten hours, and they could not be employed for a fortnight before or six weeks after confinement. By an emergency law of August 4th, 1914, the Imperial Chancellor was given power to suspend some of the provisions of the industrial law, among others those relating to women's labour. The result appears to have been very serious, long hours, and night shifts becoming general, and in some cases it was stated that women were being kept at work in factories for 24 hours at a stretch, and in mines for 36 hours, without a proper rest. Representations to the Government seem merely to have called forth circulars from the War Bureau at intervals in 1917, urging the responsible officials in various districts to do all they could to bring about improvements. The condition of women workers appears to have been much worse in Germany than either in France or England.

The original report contains an immense amount of information and a wealth of detail, and is well worth careful study.

## SCHOOL MEDICAL INSPECTION, 1918.

BIRMINGHAM—BRISTOL—HULL—LIVERPOOL—  
NOTTINGHAM—SHEFFIELD.

FOR the city of *Birmingham* the report of the medical officer dealing with health conditions in schools is very brief, owing to conditions connected with the war. The total number of children medically examined was 35,269; 2314 were treated for scabies and 1021 for throat affections (enlarged tonsils and adenoids). A school for physically defective children and an open-air school at Uffculme have been carried on with much benefit to the children admitted. Dr. Lewis Graham alludes in his report to the important results likely to be obtained in the nursery schools, for the accommodation of children between 2 and 5 years of age, that are to be established according to Section 19 of the Education Act (1918). It is stated that "the number of children reported as necessitous and in need of food" decreased during 1918. Actual ratios of malnutrition are not supplied. Considering the circumstances of the times this is to be regretted.

At *Bristol* the work has been considerably interfered with by changes in the medical staff, due to the war; school attendance was also interrupted by an outbreak of influenza in October and November. On the other hand, by an augmentation of the nursing staff more frequent supervision in the schools, and a better following up of the children at their homes has become possible. A new central clinic has been opened, which is stated to be a great improvement on former arrangements. Routine inspection of infants had to be given up, only special cases of "ailing children" brought forward by the head teachers being examined. The total number examined in the code groups (intermediate and leavers) was 9121. The nutrition of the children appears to have been satisfactory; only 0.11 per cent. were considered to be actually badly nourished, and 3.43 per cent. "below normal." The clothing and footgear were also satisfactory in all except 1.32 per cent. for the former and 1.86 for the latter. Cleanliness was satisfactory in 98.95 per cent. for the body, and 96.70 per cent. for the head. A new clinic has been opened for minor ailments in Portland-square, which has already proved to be of great benefit, 27,109 attendances having been recorded during the year. Dr. Percy Stocks, the

acting school medical officer, draws attention to the prevalence of tuberculosis, of which 503 cases among school children had been treated during the year at the Tuberculosis Dispensary, 410 being pulmonary; the proportion found at the routine inspection was 0.72 per cent., the lungs being affected in 0.69 per cent.; an increase in open-air school accommodation is recommended, and measures are now being taken to carry this out. Open-air classes were practicable, summer camps, and organisation of boy scout troops in connexion with the schools are other excellent recommendations. The only epidemic prevalence of importance was that of influenza; 70 cases were fatal. Scabies was diagnosed in only 10 children at the routine examinations (0.11 per cent.), but 491 other children of various ages were found to be suffering from the disease and were treated at the clinics; in 1915 there had been only 53 cases altogether. Impetigo also increased from 228 cases treated in 1915 to 752 cases in 1918.

At Hull the number of children examined in the code groups was 9769; the nutrition is considered to have been "extremely satisfactory," 0.26 per cent. only having been classed as "bad" and 11.24 per cent. as below normal. These figures should be compared with those of 1913, just before the war, when 0.27 per cent. were found to be badly nourished and 14.12 below normal. Dinners were provided according to an excellent diet table; on account of the coupon difficulty no meat was given, but a menu of soup, suet pudding, lentil pie, &c., gave a daily average of proteid 0.6 oz., fat 1.6 oz., and carbohydrate 3.3 oz. per head. The education committee now provide spectacles for any child that requires them if they have not been obtained within three months of the examination when the eyesight was found to be defective; in the case of necessitous parents no charge is made, in other cases the cost is recovered. A large number of cases (541) of ringworm of the scalp were treated, a considerable increase on the number (317) in the previous year; 398 children were cured, with an average treatment through ten weeks (if the attendance was regular). A great increase of scabies has occurred; in 1914 there were 296 cases, in 1917 there were 1056, and in 1918, 1442 cases; the average period of absence from this cause was 8.5 weeks; the interference with education is obvious. Disinfection of the houses and bedding has been carried out, but there is no power to insist on the treatment of any person over school age, and, of course, reinfection occurs. Pulmonary tuberculosis was found in 16, and suspected in 61 children in the three code groups; in addition, 21 children specially examined were considered to be positively affected, and 77 others were suspected to be suffering from the disease. Two epidemics of influenza occurred in 1918, one in June and July, the second (more severe) in October and November, causing great disturbance of school work. Dr. James Fraser, the school medical officer, does not consider school closure to be of use in limiting spread of the disease.

The work of medical inspection in Liverpool schools was considerably interfered with by a severe outbreak of influenza in the autumn, necessitating school closure for four weeks; medical treatment was only slightly interrupted. The total number of children examined in the code groups was 24,252. Actual malnutrition was only present in 0.132 per cent.; in 0.334 per cent. the child's nutrition was not satisfactory, without being actually in need of treatment. Scabies is stated to have been very prevalent (1179 cases, as compared with 512 in 1916 and 851 in 1917, p. 5 of report; in Table II., p. 17, it is stated that 44 cases were found among the code-group children and 49 among those specially examined); the need for suitable facilities for treatment is urgent. Baths and disinfectants are required. "Approximately 500 children were away from school at the end of the year with this disease. .... The gain in increased Government grant would probably more than make up for the cost of installation and administrative expenses of the special centre or centres." Arrangements were made for the special inspection of children absent from school for a long time, such as cases of ringworm, of phthisis or other tuberculous infection, &c. 3988 children were examined, of whom 1111 were found fit to attend school. With regard to operation for adenoids and enlarged tonsils, Dr. E. W. Hope, who presents this report, notes that in 37 cases (4 per cent.) hæmorrhage occurred, and in 11 instances it was necessary to keep the children at the clinic for two nights instead of one. "Experience has proved

the desirability of not allowing any children to return home until the following day, as it is quite impossible to forecast which children, if any, are likely to suffer from hæmorrhage or collapse." This is a very wise precaution, not always adopted. Two outbreaks of influenza during the year made the closing of several schools necessary—16 in July, 27 in September; and at the beginning of October all the elementary schools in the city were closed for a month.

In an introductory letter to the education committee of the corporation of Nottingham, Dr. Philip Boobyer, the medical officer of health for the city and superintendent medical officer of schools, refers to the need for radical improvement in the conditions of life of the industrial classes, especially in the densely populated urban districts, which has been brought home to everyone by the large proportion of men of military age who have been found unfit for military service. This is largely the result of heredity, but improvements in the conditions of the working classes in our great cities are more practicable at the present time than any attempt at restrictions on matrimony for eugenic reasons. The provision of better dwellings is of the first importance, and as regards the elementary school child the open-air schools have done excellent service. The number of children inspected in the code groups was 5137, all entrants, no leavers being examined. This was on account of ill-health of the staff, the prevalence of epidemic disease, and school closure for various reasons; but a large number of other children (7255) were examined as special cases at the clinics. Malnutrition was present in 132 cases (2.56 per cent.), and in addition 2.10 per cent. were not considered satisfactory in this respect. Scabies was not excessively prevalent (58 cases, 1.12 per cent.) in the children of the age-group examined, but altogether 843 children were under treatment, of whom 72 per cent. were cured. Dr. E. M. Wyche, the senior school medical officer, refers to the difficulties attending treatment, and the immense loss of school time involved, chiefly owing to repeated reinfection at the home. The matter is of serious importance: the total number of children excluded school for all causes during 1918 was 1650, with a loss of 83,369 school days. 841 of these children were excluded for scabies, and 39,652 actual school days were lost for this reason, involving a loss of £413 attendance grant. This is an excellent use of the *argumentum ad crumenam*, which might well be applied to the negligent parents. Ringworm has been most successfully treated by the education committee's X ray department, 192 children having been treated during the year without a single failure: radiant heat has been used to restore the growth of the hair, also for alopecia areata. Open-air education is carried on in several of the recreation grounds and open spaces in the city, and seven open-air class rooms have been erected for specially selected delicate children. The work of medical inspection, treatment, and after-care, is evidently carried out with great thoroughness and enthusiasm in the city of Nottingham.

Owing to the absence of 12 medical officers on military service routine medical inspection was suspended in Sheffield during 1918, but 16,956 "selected cases" were examined in school, as well as over 25,000 at the various clinics. Malnutrition was only found in 28 children, and in six others the nutrition was not satisfactory. Dr. Thomas Chetwood, the school medical officer, referring to this question of nutrition, states that during 1918 there was a decided improvement, as shown by the weights of the children (taken regularly every six months). The total number of dinners and breakfasts served at the feeding and school centres was 89,733, being a decrease of 54,474 on the number provided in 1917. Scabies is reported in 2304 children. The method of treatment is described by Dr. E. F. Skinner. It was extremely thorough and yet simple. The parent is instructed to attend at the cleansing station at a fixed time and to bring a set of clean underclothing (in addition to the clothes worn by the child). The child is undressed, and both sets of clothing submitted to steam sterilisation for an hour while the child is being treated. After rubbing down with soft soap the child is placed in the bath for 20 minutes and well rubbed with a loofah; after the bath the skin is rubbed with sulphur ointment, the cleansed and sterilised clothing, powdered with sulphur, is put on, and the child leaves, taking another set of sterile clothes with it. Printed instructions and sulphur ointment and powder are given to the parent, who is told to repeat the process each day. The children are seen by the doctor at

the end of a week, and, if fit, are sent back to school. "The treatment is simple, and its efficiency has been abundantly proved by this year's experience. .... The average time of exclusion is only 11.98 days." With ordinary treatment at home with ointment, the average absence has been 56 days. The secret of successful treatment is to take all the infected children in a family at the same time, but a large measure of success depends on the efficacy of the rubbing.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

### *The Public Health (Pneumonia, Malaria, Dysentery, &c.) Regulations (Scotland), 1919.*

THIS Order is closely similar to that issued in February last by the English Local Government Board.<sup>1</sup> It makes notifiable all cases of malaria, dysentery, trench fever, acute primary pneumonia, and acute influenzal pneumonia. Notification is not required in cases of malaria, dysentery, or trench fever, which to the practitioner's knowledge have been already notified within the preceding six months. The medical officer of health for the district, on receiving the notification, is to take any necessary steps to prevent the spread of the disease. He is to forward to the Board the name and address of the patient in cases of (a) trench fever; (b) malaria, where the infection was apparently contracted in this country; and (c) dysentery. The Order proceeds:—

*Malaria.*—The M.O.H. is to take steps to see that the person affected is supplied with efficient mosquito netting, receives necessary quinine treatment, receives proper advice as to the continuation of quinine treatment in order to prevent relapses, and advice as to precautions to prevent the spread of infection. On the occurrence of two or more cases in a district where the disease appears to have been locally contracted the local authority may, and if required by the Board shall, appoint and pay an approved medical practitioner to make systematic visits to houses where the disease has occurred, and offer to examine therein persons suspected of being infected with malaria, examining the blood, and further making certain that proper treatment and preventive measures are being carried out.

*Dysentery.*—The M.O.H. may give notice in writing that until further written notice the person specified shall discontinue any occupation connected with the preparation or handling of food or drink for human consumption, that children of or in the care of the said person shall not be sent to school, and that certain specified measures are taken for the destruction of excreta and prevention of infection. If the M.O.H. suspects that any person employed in the preparation or handling of food or drink for human consumption is a carrier of dysentery he may give notice in writing to the manager of the trade or business concerned, certifying that for prevention of the spread of disease he considers it necessary to make a clinical examination of such suspected person, and the manager and all other persons concerned shall give to the M.O.H. all reasonable assistance. If the suspected person be found to be a dysentery carrier notice may be given to the person and to the manager of the trade or business, with a view to preventing the employment of the said person in that or any other business concerned with the preparation or handling of human food for a specified period.

*Trench fever.*—Special measures are to be taken for the destruction of lice, and inmates of the house may be temporarily segregated until their clothing has been completely freed from vermin.

In the case of enteric fever the regulations are the same as for dysentery. Where typhus fever or relapsing fever is found, the names of infected persons are to be transmitted to the Board, and the same measures for the destruction of lice as in trench fever are applicable. Expenses incurred by the Medical Officer of Health are to be defrayed by the local authority concerned, and they may also provide medical assistance where necessary in cases of the diseases specified.

### *Organised Health in Edinburgh.*

Some extremely interesting facts and figures are contained in a report prepared by Councillor J. A. Young, L.D.S., convenor of the Public Health Committee of Edinburgh Town Council, on the progress of health administration in the city. The first record available regarding public health work is dated 1812–13, when the Police Commissioners undertook the scavenging of the city, the watering of the streets, and the building and maintenance of public conveniences. The cholera epidemics in the early part of the century seem to have been dealt with by voluntary workers in special hospitals, but it was not until the outbreak of 1866 that a hospital was provided at public expense. There was not until 1870 any public provision for the treatment of infectious diseases, and at that date it was only furnished for cases of small-pox. The late Sir Henry

Littlejohn was appointed medical officer of health in 1862, and immediately undertook a thorough survey of the sanitation of the city. His report was published in 1865, and taking the figures for 1863, it gives a picture of the actual condition of affairs at the time of the formation of the department. In 1861 the population of the city was 170,444, and the death-rate 25.88 per 1000; in 1911 the figures were 320,829 and 14.39 respectively, this reduction in the death-rate being equivalent to the saving of 3673 lives per annum on the increased population. Deaths under 5 years of age show an enormous reduction, from 93.29 per 1000 living in 1863 to 33.6 per 1000 in 1913. In 1863 the death-rate from zymotic diseases was equal to 6.23 per 1000; in 1913 to 0.87; many of the diseases then chiefly responsible—cholera, typhus, &c.—have now practically disappeared. The phthisis death-rate in 1863 was 2.54 per 1000; in 1913 the figure was 1.13. The general sanitary condition of the city shows corresponding improvement. In 1863 the most densely crowded district had a population of 646 persons per acre; the highest figure at the present day being 343. The internal condition of the tenements in 1863 was in many instances appalling. Sir Henry Littlejohn mentions one known as Middle Mealmarket Stair, in which 248 persons were housed, and which was unprovided with sink or water-closet. Of 171 cow-byres then existing, 110 were below human dwellings, and many of them filthy and overcrowded, with the cows dying off from pleuro-pneumonia. A comparison of the finance of the department shows an average expenditure for the last nine years of £36,778, as compared with an average for the ten years to 1889 of £5365.

### *Edinburgh Royal Infirmary: Retirement of Professor William Russell and Dr. Graham Brown.*

At the meeting of managers held on Sept. 8th special minutes were passed expressing regret at the retirement of Professor William Russell and Dr. Graham Brown, and placing on record the valuable services which these gentlemen have rendered to the institution. Professor Russell first became a member of the staff in 1888, when he was appointed pathologist to the infirmary, a position which he held for four years. In 1891 he became assistant physician, and in 1907 full physician in charge of wards. In 1913 he was appointed by the University the first occupant of the Moncrieff-Arnott chair of Clinical Medicine. In all these positions he performed his duties with efficiency and zeal, and in consideration of his eminent services the managers of the Royal Infirmary have appointed him a consulting physician to the institution. Professor Russell's successor as Moncrieff-Arnott professor of Clinical Medicine is Dr. F. D. Boyd, whose appointment has been previously announced. Dr. Graham Brown was appointed assistant physician to the infirmary in 1897, and full physician in 1912. He has also held the position of lecturer on neurology in the University for a number of years, and is well known for his special ability in this branch of medicine. In recognition of his services to the institution Dr. Graham Brown was appointed a consulting physician to the Royal Infirmary.

### *Criminal or Spontaneous Abortion?*

On Sept. 9th and 10th, in the High Court of Justiciary at Edinburgh, a woman was tried for causing the death of a young clerkess by performing an illegal operation. The case is of interest from the fact that the deceased, who was about four months' pregnant, had placenta prævia, and also because of the absence of any wound of the private parts, and the assertion of the Crown that the attempted abortion had been made by means of an injection into the womb from a Higginson's syringe. At the post-mortem, made by Professor Littlejohn and Dr. Haig Ferguson, there was found dilatation of the os and cervix, absence of the usual plug of mucus in the cervix, and partial detachment of the placenta around the internal os. There was evidence of considerable loss of blood, and the medical witnesses ascribed death to hæmorrhage and shock. All the internal organs were healthy, and no other conditions to account for death were found. The deceased went by arrangement to the house of the prisoner one evening about 5.30; she was then in good health, and there was no history of previous illness or hæmorrhage. She was quite well at 9 P.M. except for slight sickness, alleged to be due to some strawberries and cream which she had eaten a short time earlier. At 9 P.M. deceased went to bed and the prisoner spent a quarter of an hour with her alone.

<sup>1</sup> THE LANCET, 1919, i., 303, 309.

The young woman then became ill, vomited, and was collapsed, and died about 11 P.M. A Higginson's syringe in a basin of water was seen in the room immediately after the prisoner had been with her. Three obstetricians who appeared for the defence contended that the appearances were quite consistent with impending spontaneous abortion. The jury unanimously found the prisoner guilty of culpable homicide and she was sentenced to five years' penal servitude.

Sept. 15th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

### *The Health Department of Canada.*

THE Hon. Newton W. Rowell has been placed in charge of the organisation of Canada's Department of Health, authorised by special legislation at the last session of Parliament. Dr. John Amyot, who has been appointed Deputy Minister, was formerly professor of hygiene and public medicine in the University of Toronto. The new department is taking over from other departments of Government administration those branches which concern the health of the people, such as quarantine, marine hospitals, the health of the Indians. Immigration was the first to be brought over to the new department. The question of co-operation with the various boards of health of the different provinces is claiming the particular attention of the Deputy Minister with a view to co-operation in the campaign against venereal diseases. The policy of the department will be shortly announced to the public.

### *Hospitals in Montreal and Toronto.*

A number of citizens have become interested in a new hospital scheme for Montreal. It is to be known as the St. Mary's Memorial Hospital, and is to perpetuate the memory of relatives who lost their lives in the Great War. The hospital will be open to all classes and creeds in the community. An appeal for funds will be made in October. Many Montreal families have already promised to endow beds. Montreal is in great need of enlarged hospital accommodation.

Mr. William Ramsay, formerly a Toronto wholesale merchant and director of many commercial concerns, died recently in Scotland. He left over half a million dollars to Toronto charities—the General Hospital, \$10,000 a year; Home for incurables, \$5,000.

### *Public Welfare in Alberta.*

The Department of Public Health of Alberta province, under the responsible Minister, Hon. A. G. Mackay, and Deputy Minister, Dr. J. T. Normau, has recently been given power by the Legislature to prevent, mitigate, or suppress disease. It can deal with all epidemics, and, if necessary, order, in the case of small-pox, general vaccination of all communities affected. It is handling the venereal diseases problems, and it is seeing that the provisions of the Provincial Health Act are applied when necessary.

The war being over, the Canadian Public Health Association is showing signs of new life. Dr. H. E. Young, secretary of the Provincial Board of Health of British Columbia, was elected president at the last annual meeting, held for the present year in Toronto. Edmonton, Alberta, was chosen as the place of meeting in 1920. Alberta has more trouble in health matters with the 33.6 per cent. foreign-born population than with the remaining 66.4 per cent. British-born, owing to the foreigners holding to their traditions and refusing to adopt up-to-date methods in vogue in Canada.

Toronto, Sept. 1st.

## Public Health.

### REPORT OF THE LONDON COUNTY COUNCIL'S MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER FOR THE YEAR 1918.

Dr. W. H. Hamer's annual report on the health of the metropolis during 1918 contains a great deal of interesting material. It appears that in 1918, for the first time in records going back nearly a century, the deaths in London exceeded the births. Two causes contributed to this result—namely, the reduction in births brought about by the war and the large number of deaths from the two epidemics of influenza. The deaths among civilians alone during the year outnumbered the births by nearly 5000, and to this figure must be added a number of deaths among Londoners on active service. In the first week of November, when the second epidemic of influenza reached its height, the death-rate in London was 55.5 per 1000. This is the highest rate recorded in any week since the cholera year of 1849, in the thirty-sixth week of which 3183 deaths were registered, giving a rate of over 72 per 1000. The total number of deaths among civilians in 1918 numbered nearly 76,000, and of this total it is estimated that not fewer than 18,000 were due to the influenza epidemics. The infant mortality was 108, showing a slight increase on the rate of 104 per 1000 births in 1917.

### *Notifiable Infectious Diseases.*

The remarkably low prevalence of notifiable infectious diseases in London in recent years was maintained in 1918. Several groups of small-pox cases, however, gave cause for anxiety, but happily in each instance prompt measures of isolation were effective in limiting the spread of the disease. Diphtheria was less prevalent than in 1917, and, while there was a slight increase in the number of cases of scarlet fever, the total was nevertheless far below the average. There was an increase in the deaths from dysentery, which amounted to 313, as compared with 290 in 1917, the increase being in female deaths, while the male deaths showed a decline. There were no recognised outbreaks due to importation of the disease from abroad, such as occurred in two boroughs in 1917. The incidence of typhoid fever was very low. Cerebro-spinal fever was less prevalent than in 1917, and poliomyelitis and poliomyelitis were at a comparatively low ebb. There were, however, a few cases of encephalitis lethargica which might formerly have been described as poliomyelitis. There was some increase in the number of cases of pulmonary tuberculosis notified, both among males and females, mainly in the first half of the year. The mortality was also higher than in 1917, but this increase was largely due to the influenza epidemics.

### *Fleas and Scarlet Fever.*

In recent annual reports by Dr. Hamer the relationship of scarlet fever to rainfall and flea prevalence was discussed. The present report contains a diagram showing the seasonal prevalence of fleas over a series of years and the incidence of scarlet fever and diphtheria in the corresponding period. The diagram is divided into two sections; the first shows the monthly prevalence of fleas in relation to the monthly case rates of scarlet fever and diphtheria during the ten years 1909-18. A small inset diagram gives the mean monthly rates for the ten years, and as the maximum seasonal incidence of scarlet fever cases is about one month later than the maximum prevalence of fleas the case-rates are ante-dated one month to facilitate comparison. The second section of the diagram is designed to illustrate how far a deviation from the average quarterly incidence of flea prevalence is associated with a corresponding deviation from the average quarterly incidence of scarlet fever, as well as at all ages as in certain age-groups; the average for diphtheria at all ages being also shown. The contour of flea prevalence is based upon figures which post-date by one month the figures for scarlet fever and diphtheria. The first section of the diagram shows a greater measure of association of annual prevalence of fleas with scarlet fever than with diphtheria. The three years of highest prevalence of scarlet fever and fleas (1913-15) are followed by three years of relatively low incidence, but in diphtheria the correspondence is not so close. In some years there is a secondary prevalence of

**EDUCATIONAL GRANTS FOR EX-SERVICE MEN.**—Under the Government scheme of financial assistance for the higher education of ex-Service officers and men the total number of grants awarded by the Board of Education now amounts to 9500, including 4000 officers and 5500 men. The courses in respect of which grants have been awarded include more than 2500 for engineering and technological subjects, between 800 and 900 for classics, philosophy, and literature, and about 1200 for pure science and mathematics. Applications are still being received in large numbers, and are being dealt with at the rate of more than 100 a day.

diphtheria following the normal autumn incidence, and in 1914 the February case-rate of diphtheria exceeded the normal autumnal maximum of the preceding October. There is no evidence of any similar secondary prevalence in the case of scarlet fever, although the decline after the normal autumnal maximum is not equally regular in all years.

In the second section of the diagram the average figures for each quarter are taken as a basis in order to eliminate the wide fluctuations of monthly records. The diagram shows the extent of deviation in any first quarter from the average of nine first quarters in the period 1910-18, and so on for other quarters. The general similarity of the contours of the flea and scarlet fever prevalences is significant, especially in view of the less-marked correspondence shown in the case of diphtheria. In view of the interval of about a month between the maxima of flea and scarlet fever prevalence, the question arises whether the interval points to the fact that there are two distinct phenomena controlled by one factor (such, for instance, as meteorological conditions), or whether a part of the interval can be taken to represent evolution of a scarlet fever germ. In either case the facts, in Dr. Hamer's opinion, imply that the conditions which favour flea prevalence are either identical or intimately associated with those influencing prevalence of scarlet fever, and a presumption is raised that steps directed to the elimination of fleas may loosen the foothold of scarlet fever. Effect is, as far as practicable, being given to this view in London at the present time. There was, for example, prevalence of scarlet fever in Southwark in the summer of last year. The outbreak occurred at a time when the amount of scarlet fever in London as a whole was relatively small. The area affected was very limited, but the incidence within the area was very high. Application was made to the borough council to disinfect the infants' department of the council's school central to the area, the records of which showed a greatly excessive proportion of flea-bitten children. This was done, and, in addition, the officers of the borough council visited homes and disinfected rooms and bedding associated with scarlet fever cases. This action was followed by marked reduction of prevalence of scarlet fever.

#### Influenza.

A special report on the three widespread influenza epidemics of 1918-19 is given in the appendix. The report is divided into two parts—namely: (1) a review of recent epidemic prevalences; and (2) a study of the light thrown on these epidemics by earlier prevalences, with a summary view of the epidemiology of the influenza group of diseases. If the subject is to receive adequate treatment, Dr. Hamer urges the necessity for "extensive and peculiar" knowledge of the epidemiology of past epidemics of influenza in London, and expresses the opinion that the subject must be approached from the natural history point of view. As Creighton has said in another connexion, the older or Hippocratic method must be applied. This is one which "took account of gradations, modifications, affinities, being careless of symmetry, of definitions, or clear-cut nosological ideas, or the dividing lines of a classification." The attempt to comply with such conditions will involve reference to the sweats, agues, spotted fevers, and lethargies of the earlier centuries; then, throughout, to obscure pneumonias, certain outbreaks of "typhus" and various "new diseases." The special report on influenza contains many valuable suggestions, and is worthy of the careful consideration of all epidemiologists.

### URBAN VITAL STATISTICS.

(Week ended Sept. 13th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.0, 10.0, and 10.7 in the three preceding weeks, fell to 10.4 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 10.9, or 0.4 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 5.6 in Wallasey, 5.9 in Huddersfield, and 6.0 in East Ham and in Bury, to 16.3 in Tynemouth, 17.1 in South Shields, and 19.3 in West Hartlepool. The principal epidemic diseases caused 313 deaths, which corresponded to a rate of 1.0 per 1000, and included 241 from infantile diarrhoea, 26 from diphtheria, 17 from whooping-cough, 15 from measles, 11 from scarlet fever, and 3 from enteric fever. Measles caused a death-rate of 1.3 in Barrow-in-Furness and in Gateshead. There were 1504 cases of scarlet fever and 1057 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1454 and 1006 respectively at the

end of the previous week. The causes of 16 deaths in the 96 towns were uncertified, of which 4 were registered in Liverpool, 3 in Tynemouth, and 2 in Birmingham.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 10.7, 10.9, and 10.8 in the three preceding weeks, fell to 10.2 per 1000. The 222 deaths in Glasgow corresponded to an annual rate of 10.3 per 1000, and included 20 from infantile diarrhoea, 4 from diphtheria, 3 from whooping-cough, 2 from measles, and 1 from scarlet fever. The 68 deaths in Edinburgh were equal to a rate of 10.5 per 1000, and included a fatal case each of measles and diphtheria.

*Irish Towns.*—The 134 deaths in Dublin corresponded to an annual rate of 17.3, or 2.4 per 1000 below that recorded in the previous week, and included 7 from infantile diarrhoea, and 1 each from enteric fever and diphtheria. The 100 deaths in Belfast were equal to a rate of 13.0 per 1000, and included 10 from infantile diarrhoea, and 2 each from enteric fever and scarlet fever.

## The Services.

### THE HONOURS LIST.

The following awards to medical officers in connexion with military operations in India and in Persia are announced:—

*C.I.E.*—Capt. J. B. Hanafin, I.M.S.; Lt.-Col. J. B. Jameson, I.M.S. (ret.); Maj. L. Hirsch, I.M.S.; Lt.-Col. S. J. Rennie, R.A.M.C. (ret.); Lt.-Col. J. W. Watson, I.M.S.

*C.S.I.*—Col. A. E. Tate, C.M.G., A.M.S.

*C.B.E.*—Maj. and Bt. Lt.-Col. (temp. Col.) F. A. F. Barnardo, C.I.E., I.M.S.

*O.B.E.*—Capt. (temp. Maj.) A. F. Babonau, I.M.S.; Temp. Capt. J. Cairns, R.A.M.C. (T.F.); Capt. (temp. Maj.) F. R. Coppinger, R.A.M.C.; Maj. (temp. Lt.-Col.) J. K. S. Fleming, I.M.S.; Maj. G. D. Franklin, I.M.S.; Maj. A. T. Frost, R.A.M.C.; Capt. W. A. Frost, R.A.M.C.; Capt. T. B. Heaton, R.A.M.C. (S.R.); Maj. D. P. Johnstone, R.A.M.C.; Maj. T. W. Minty, I.M.S.; Lt.-Col. P. St. C. More, I.M.S.; Maj. R. B. Nicholson, M.C., I.M.S.; Maj. H. W. Pierpont, I.M.S.; Lt.-Col. J. J. W. Prescott, D.S.O., R.A.M.C.; Capt. C. H. Smith, I.M.S.; Capt. (temp. Maj.) J. R. D. Webb, I.M.S.

*M.B.E.*—Lt. (temp. Capt.) P. X. Godinho, I.M.S.

*Military Cross.*—Temp. Lt. Mahomed Nawaz, I.M.S.; Capt. R. R. M. Porter, I.M.S.

*To be Brevet Lieutenant-Colonel.*—Maj. N. W. Mackworth, I.M.S.

*To be Brevet Major.*—Capt. J. A. A. Kernahan, I.M.S.; Capt. (temp. Lt.-Col.) J. V. Macdonald, M.C., I.M.S.; Capt. (temp. Maj.) M. A. Rahman, I.M.S.; Capt. (temp. Maj.) E. E. Doyle, I.M.S.; Capt. (temp. Maj.) C. Ryles, R.A.M.C.; Capt. (temp. Maj.) W. R. Stewart, I.M.S.

### ARMY MEDICAL SERVICE.

Major-General Sir M. T. Yarr, C.B., K.C.M.G., to be Inspector of Medical Services (temporary), vice Major-General Sir W. Battie, V.C., K.C.M.G., C.B., K.H.S.

Temp. Cols. Sir T. C. English, K.C.M.G. (Captain, R.A.M.C., T.F.), and Sir C. A. Ballance, K.C.M.G., C.B., M.V.O. (Captain, R.A.M.C., T.F.), relinquish their temporary commissions on re-posting.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. O. W. A. Elsuier relinquishes the temporary rank of Colonel on re-posting.

The undermentioned relinquish the acting rank of Lieut.-Col. on re-posting: Majors G. H. Stevenson, T. F. Ritchie, P. J. Maret; Temp. Capt. J. Scott, D. Miller.

The undermentioned to be acting Lieut.-Colonels whilst commanding Medical Units: Capt. (acting Major) R. G. Shaw; Capt. E. Percival, T. S. Eves; Temp. Capt. (acting Majors) H. C. Watson, J. P. Davidson; Temp. Capt. G. Jackson.

Temp. Major E. W. H. Groves (Captain, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

The undermentioned relinquish the acting rank of Major: Capt. J. E. Hepper (on ceasing to be specially employed); Temp. Capt. A. W. Tabuteau, L. ap. I. Davies, W. H. Clements, J. M. Morris, W. J. J. Arnold, C. Roche, A. L. Krogh (on re-posting); Temp. Lieut. G. E. Froggatt.

To be acting Majors whilst specially employed: Capt. S. H. Smith, F. Worthington, R. E. Todd, H. F. Joynt; Capt. and Bt. Major T. A. Weston; Temp. Capt. H. G. Gillies, A. L. Robinson, S. S. Dunn, G. Cooper, H. M. Anderson, C. E. Waldron.

Capt. T. D. Inch resigns his commission.

Temp. Capt. (acting Major) R. Jamison to be acting Lieutenant-Colonel whilst specially employed.

Temp. Capt. J. H. G. Hunter and J. McFadden to be Captains.

The undermentioned late temporary Captains to be temporary Captains: L. Gibbons, R. A. Flynn, T. F. Griffith, J. Joule, C. L. Driscoll.

Officers relinquishing their commissions: Temp. Lieut.-Col. and Hon. Lieut.-Col. W. I. de C. Wheeler (retains the rank of Lieutenant-Colonel); Temp. Lieut.-Col. E. J. Moore, Temp. Lieut.-Cols. G. E. Miles and C. T. Parsons (retain the rank of Lieutenant-Colonel); Temp. Hon. Lieut.-Cols. G. S. Buchanan and J. Robertson (retain the honorary rank of Lieutenant-Colonel); Temp. Hon. Lieut.-Col. H. R. Kenwood (Major, R.A.M.C., T.F.) (relinquishes his temporary commission on re-posting). Temporary Majors retaining the rank of Major: T. M. Kendall, P. J. A. Secombe. Temporary Captains granted the rank of Major: J. Crawford, R. E. Cree. Temporary Captains retaining the rank of Captain: A. W. George, D. Corry, W. E. Morgan, W. F. Thompson (acting Major); J. E. L. A. Turnley, R. M. Gordon, F. F. C. Willington, W. G. Shaw, J. G. Shanklin, G. L. Keynes, C. J. Glasson, J. M. Christie, S. C. H. Moberly, E. R. Wheeler, E. M. Brown, J. A. Wilson, F. W. Jones, C. J. Heaton, J. D. Carroll, R. A. Banbury, A. Poole, P. B. Whittington, J. C. Fergusson, J. Prichard, W. D. Lawrie, W. McFarlane, G. Hoffmann, C. Gray, H. C. Hinwood, W. C. P. Barrett; Temp. Hon. Capt. W. A. Pride (retains the honorary rank of Captain); Temp. Lieut. R. M. D. Devereux and W. H. Newton (retain the rank of Lieutenant).

*Canadian Army Medical Corps.*

Temporary Lieutenant-Colonels (acting Colonels) to be temporary Colonels: C. P. Templeton, E. L. Stone.

Temporary Majors (acting Lieutenant-Colonels) to be temporary Lieutenant-Colonels: J. S. Jenkins, C. Hunter, W. T. Lockhart, C. F. L. Haszard.

Temp. Major (acting Lieut.-Col.) L. H. McKim relinquishes the acting rank of Lieutenant-Colonel.

The undermentioned temporary Captains (acting Majors) relinquish the acting rank of Major: J. G. Shaw, J. Pullar.

The undermentioned temporary Captains (acting Majors) to be temporary Majors: D. S. Lewis, S. Sprague, G. O. Scott, H. W. Wadge, P. J. S. Bird, J. D. Jones, J. S. Fitzsimmons, J. W. Hunt, A. B. Wilkes, B. R. Almquist.

Temp. Capts. (acting Majors) E. F. Risdon and R. A. Thomas relinquish the acting rank of Major.

Temp. Major N. G. Cooper and Temp. Capt. H. W. Bell retire in the British Isles.

*South African Medical Corps.*

The undermentioned relinquish their commissions and retain the rank of Captain: Capt. J. McL. Hendry; Temp. Capts. E. W. Dyer, J. I. de Villiers, E. Wolff, A. S. Wilson, G. H. Coke.

## GENERAL RESERVE OF OFFICERS.

T. D. Inch, late Captain R.A.M.C., to be Captain.

## SPECIAL RESERVE OF OFFICERS.

Capt. L. C. Rudd and E. R. Chambers relinquish their commissions. Capt. R. T. C. Robertson relinquishes the acting rank of Lieutenant-Colonel on ceasing to command a Medical Unit.

Captains relinquishing the acting rank of Major on ceasing to be specially employed: H. C. G. Pedler, R. O. C. Thomson.

Captains to be acting Majors: D. McIntyre, J. J. McI. Shaw (whilst specially employed).

## TERRITORIAL FORCE.\*

Major M. G. Foster is restored to the establishment on ceasing to hold a temporary commission in the Army Medical Service.

Capt. (acting Lieut.-Col.) J. Barkley, D.S.O., and W. D. Sturrock relinquish their acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Capt. (acting Majors) J. L. M. Symms and L. E. Hughes relinquish their acting rank of Major on ceasing to be specially employed.

4th London General Hospital: Major W. A. Turner is restored to the establishment on ceasing to hold a temporary commission in the Army Medical Service.

2nd London Sanitary Company: Capt. (acting Major) A. G. G. Thompson relinquishes the acting rank of Major on ceasing to be specially employed.

## ROYAL AIR FORCE.

*Medical Branch.*—Capt. (acting Major) C. J. G. Taylor (Surgeon-Lieut., R.N.V.R.) relinquishes his commission on ceasing to be employed.

The undermentioned are transferred to the unemployed list: Capts. Wm. S. T. Connell, T. R. Hunter, W. H. Cam.

## INDIAN MEDICAL SERVICE.

To be acting Lieutenant-Colonels while commanding Medical Units in the Field: Majors F. H. Stewart, S. H. L. Abbott, Capts. A. G. Coullie, J. B. Lapsley, J. Portelli to be temporary Lieutenant.

## DEATHS IN THE SERVICES.

Fleet Surgeon George Hewlett, R.N., died on August 26th at Andover as a result of a collision between the motor-bicycle he was riding and a motor-car four days previously. As a student in Edinburgh he surprised some by graduating after four years' study with first-class honours, but he was very shrewd, had an alert mind and a retentive memory. A Cornishman, he went at once to sea, first in the merchant service, and later in the Navy, where he did a great deal to keep a friendly spirit alive in the ships in which he served. His loss will be keenly felt by his old shipmates. He was by nature a man of the wild, and after leaving the service spent a year fishing and shooting in British Columbia. His alternative employment was the sailing of his yacht about the Channel. For three years of the war he served as fleet surgeon of Portsmouth Dockyard.

THE LATE MR. EDWIN O. SACHS, F.R.S.E.,  
CHAIRMAN OF THE BRITISH FIRE PREVENTION COMMITTEE.

—Mr. Sachs, who died at his residence in Portland-place on Sept. 9th at the early age of 49, practised for several years as an architect and was the author of a standard work, "The Modern Opera House and Theatre." He was the first in England to apply electrical power to the working of the stage, and the "Sachs System" has been adopted by Covent Garden Opera House and the Theatre Royal, Drury-lane. It is, however, by his keen interest in regard to fire protection that he will be most remembered. Realising that the great loss of human life and property due to fire might be much reduced by legislation and ordinary measures of precaution, he devoted his time to propaganda work in this direction, and helped to procure preventive legislation by which loss of infant life due to the use of inflammable clothing could be minimised. His activities, which were entirely voluntary, extended to many other countries besides the British Isles, and he was vice-president of the International Fire Service Council. During the war the committee of which he was chairman made arrangements for a voluntary survey force for over 2000 war hospitals, camps, and factories. He initiated or guided work of high importance to the nation in circumstances of ill-health attended by much suffering.

## Correspondence.

"Andi alteram partem."

THE BRITISH FEDERATION OF MEDICAL AND  
ALLIED SOCIETIES.

To the Editor of THE LANCET.

SIR,—A letter from Dr. E. R. Fothergill was published under the title "The Cult of Individualism" in the issue of the *British Medical Journal* dated Sept. 13th. That communication contained so many inaccuracies and mis-statements that we would request space in your valued columns to correct any false impressions that may have been occasioned by it. Seeing that no issue exists between the British Medical Association and the Federation of Medical and Allied Societies (late Medical Parliamentary Committee), of the former of which we are also members, we are not concerned with the defence of the body we represent. In the first place we do not subscribe to the wholesale condemnation of the Association contained in the fourth paragraph of Dr. Fothergill's letter. And we cannot agree that the British Medical Association "is now recognised by all departments in the State as the mouthpiece of the profession," much as we might wish it to be. Apart from the fact that the Medical Directory contains the names of twice the number of medical men that the membership of the Association embraces, there are several other professional bodies that the Government departments consult direct. The policy of the Federation can in no way be construed as making for rivalry with the Association; the aims of the former are definite in extent. It provides a permanent "round table" at which representative doctors, of all shades of opinion and engaged in all branches of medical work, may meet and confer with one another and with the representatives of lay bodies whose activities are ancillary to medicine; it aims at obtaining support for the profession from a much larger section of the public than any purely medical body can hope to obtain; it constitutes a "reference library" on matters affecting the public health, and by being in a position to supply information to the profession and the public, on the one side, and to those guiding legislation, on the other, it is truly a "liaison committee." Thus, in place of overlapping and confusion in policy, the Federation offers a real prospect of unity in thought and action.

Dr. Fothergill has a great deal to say regarding schisms in the ranks of the profession: it will therefore interest him to know that the three bodies he mentions and whose existence he deprecates are amongst those who have taken part in the formation of the Federation, so that already far greater unity exists than was the case prior to the formation of the Medical Parliamentary Committee. It will be time enough to discuss the objection raised regarding individual subscriptions when the Federation asks for them.

It would be well if Dr. Fothergill could understand that there are others besides himself who are working disinterestedly for the good of the profession and the community.—We are, Sir, yours faithfully,

MALCOLM MORRIS,

Chairman.

CHARLES BUTTAR,

Honorary Secretary.

N. HOWARD MUMFERY,

Organising Secretary.

The British Federation of Medical and Allied Societies,  
20, Hanover-square, W., Sept. 15th, 1919.

## CONTROL OF VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—In the account given in THE LANCET of Sept. 6th of the recent deputation of the National Council for Combating Venereal Diseases, and the reply thereto of the Public Health Committee of the London County Council, the recommendation of the last-named body is merely stated without the addition of the detailed reasons on which it was presumably based. THE LANCET account proceeds to comment on the London County Council's recommendation as indicating a "policy of passivity" in relation to the preventive treatment of venereal diseases, and apparently regards the National

Council's proposal of "treatment at an approved centre within a short time after exposure to possible infection," and its further statement that, for the effectual prevention of *syphilis*, "treatment must be initiated within six hours after exposure to risk," as embodying the only possible scheme of medical prevention.

I desire to point out that the National Council's scheme in respect to *syphilis* (as reported) gives a very wide and dangerous margin of safety in its mention of "within six hours" and says nothing of the safety margin in the case of *gonorrhoea*, which is overwhelmingly more widespread than *syphilis*. It is scarcely to be supposed that the six-hour margin is meant by the Council to apply to both cases! Further, the National Council's scheme 'not only is of very doubtful efficiency, but also involves an increased expenditure of public money out of all proportion to the slight amount of good it might possibly bring about.

Is it not probable, if not certain, that it is owing to such objections as these that the London County Council's Public Health Committee "is not satisfied that the public provision of early preventive treatment as suggested by the National Council for Combating Venereal Disease is desirable"? Or is THE LANCET's implication that the County Council's Committee is indifferent to the question of preventing the spread of venereal diseases to be preferred?

I am Sir, yours faithfully,

Sept. 11th, 1919.

H. BRYAN DONKIN.

### PROPHYLACTIC QUININE IN MALARIA.

To the Editor of THE LANCET.

SIR,—During a stay of three months in Aden I had a great deal of trouble with my servant. He was a Somali, who understood no English and no Hindustani, and who spoke worse Hindustani, if possible, than I did myself. Heated misunderstandings, no doubt aggravated by the fact that I was suffering at the time from repeated attacks of mild malaria, naturally resulted, and our relations became more and more strained.

The first step on the road to reconciliation was taken when I found that I could with absolute certainty keep myself free from malaria by taking 5 gr. of quinine daily. I then found to my shame one evening that my unfortunate servant was excusing himself for his shortcomings in a fearful jumble of tongues on the grounds that he was sick in the same way that "master" had been sick himself. Five grains of quinine daily transformed him into an intelligent and efficient valet. To save trouble I used to give him my own tablets, and when we parted, the best of friends, he begged me to tell him where they could be purchased. I explained to him, in the code we had established, that they were beyond his means and he must go to the civil hospital.

Nothing will ever persuade this Somali boy or myself that in certain circumstances there is not a type of malaria which can with certainty be prevented by quinine, and which will with equal certainty recur if the quinine is discontinued.

In view of the above domestic incidents I have read with much interest Major A. H. Gosse's article on quinine prophylaxis in your issue of Sept. 6th.

I am, Sir, yours faithfully,

Kensington, W., Sept. 12th, 1919.

J. E. SANDILANDS.

### EROSION OF THE GREAT VESSELS OF THE NECK IN SCARLATINAL ABSCESS.

To the Editor of THE LANCET.

SIR,—This condition may not be so rare as is implied in the annotation in your issue of last week. During an epidemic of scarlet fever in South Wales in 1887 I saw two cases in a fortnight, both in young children, and both rapidly fatal. One burst externally, and I concluded that it was the external carotid which was eroded.

I am, Sir, yours faithfully,

Bournemouth, Sept. 14th, 1919.

E. CURTIN.

### CRYPTOPODIA.

To the Editor of THE LANCET.

SIR,—Mr. T. S. P. Strangeways has overlooked the fact that the arthritis began 10 years later than the enlargement of the feet, and I may add that there is no trace of it in the lower limbs. Moreover, for more than 10 years past the

patient has been bedridden—i.e., living under the very conditions which Mr. Strangeways lays down as essential to cure. In the face of the very remarkable blood-count it is hard to deny the right of the condition to be regarded as a disease, and even a specific one. I especially hope that the blood-count will receive the attention that it deserves. With reference to Dr. Parkes Weber's remarks, I distinctly stated, and believe that I demonstrated to Dr. Parkes Weber personally, the very ready and deep pitting on pressure in the case under notice. This differentiates it sharply, on his own showing, from the case described by him at the Royal Society of Medicine. How my case can possibly have anything in common with one in which the enlargement consisted of "dense fibrous tissue," as described by Mr. W. Robinson in your last issue, I fail to see.

For the present, my description of my case by a new name, and as a new disease, has not been in any way shown to be unwarranted.

I am, Sir, yours faithfully,

De Crespigny Park, Denmark Hill, S.E., E. C. BOUSFIELD.

Sept. 15th, 1919.

### THE RESULTS OF COMPLETE COLECTOMY.

To the Editor of THE LANCET.

SIR,—In reference to Mr. J. E. Adams's letter in THE LANCET of August 23rd, in which he criticises me for not giving fuller details of my cases, I plead guilty, since I might have mentioned that he was the surgeon who performed the third operation on Case B.

I am, Sir, yours faithfully,

JAMES TAYLOR.

Cambridge Hospital, Aldershot, Sept. 12th, 1919.

### MIND AND MEDICINE.

To the Editor of THE LANCET.

SIR,—The adhesion of a prominent psychologist to one of Freud's main principles, noticed lately in your journal, reminds us that not so long ago a leading alienist wrote that psycho-analysis was dead in England, thanks to Dr. C. Mercier. A continental observer, if told of this, would likely enough have seen in it merely the common spectacle of a man of talent attacking a man of genius. Now, it is certain that Dr. Mercier was a man of talent, but not quite certain yet that Freud has genius. Contemporary estimates are notoriously unreliable, and, moreover, inevitably so, or mankind, which, as was long ago pointed out, whether or not it wishes to act rightly, mostly desires correct knowledge, would have improved ere this its powers of criticism of a current event or opinion. Sometimes posterity endorses contemporary verdicts, but oftener reverses them. How will it be with Freud's work? The testimony already mentioned may furnish an indication, as also the appearance of paragraphs on "repression" in the daily press—a phenomenon, this latter, of complete unimportance had it happened when Freud's name first crossed the Channel (or rather the North Sea), but of considerable significance now, after the lapse of years and the consequent test of time.

What more than his obscurity of style and the poorness of his translators has spoiled Freud's reception over here is the British ignorance that there is such a study as sexuality—or perhaps one had better say, after the last International Medical Congress in London, the British "conspiracy" (as I have seen it misspelt in a foreign journal) of silence. That ignorance or that conspiracy is perforce beginning to disappear now; still, in this country we have only yet got to the antivenereal campaign and sexual pedagogy, and to these only fairly recently; although in different booklets on the latter subject have appeared in such numbers as to suggest that their production is, if one may help oneself to a metaphor from the illustrious physician of Chinon, as easy as wetting the bed. The best book of Freud's to begin with—in fact his countrymen say his best book altogether—is the "Psycho-pathology of Everyday Life." The assertion is ventured that a single perusal of this work would make a good many partial converts. When a man sees that by the help of Freud, and of nobody else, he can account for missed trains, undated cheques, and other seemingly fortuitous slips of his daily life, he is impressed. Not that the dreaded sexual element is absent. This book, too, is not one to leave about. Sex occupies in it nearly as much space as in human thought

and conduct. One secretly fearing that his mistress has conceived makes an ordinary slip of the tongue in ordinary conversation; but it is enough for the psycho-analyst to guess his secret by. Well, these things happen and will go on happening; better to study than to snigger over them, or pretend they are non-existent.

Probably the strongest impeachment comes from the man who first in this country mentioned Freud's work, and to whom the latter paid the compliment of writing to regret that psycho-analysis did not meet with his full approval. That impeachment was, that the line of inquiry is full of risk of error; for sexual symbolism, which is central to the argument of Freud's chief work, can, like any other symbolism, be rather easily carried to an excess, become far-fetched, strained, intolerably overweening. In its simpler applications it will probably convince most unprejudiced minds, particularly in presence of the high standard of investigation some Freudian disciples attain. Take, for instance, an article in *Imago*, on the sexual symbolism of the fish, by a lesser known one. In this paper proofs, often pictorially reproduced, are drawn from prehistoric drawings, down through classic art, through mythology, anthropology, etymology, literature and folklore, to a quotation (about Montenegrin water-bailiffs) from *Country Life*, of all sources—and the editors in a fine spirit of team work add others. It is difficult to doubt, after reading this multifarious evidence of the world-wide association of the fish with erotic deities, and those presiding over increase and fertility, as also with marriage ceremonies, that the author has made out a strong case. Again, others besides Freud rely on sexual symbolism. In view of the mention of religion in your article the following two instances come in well. A reviewer in *The Expository Times* has written: "..... the Bible is full of symbols and we have lost their language. We are very prosaic. The writers of the Old Testament and of the New were very imaginative. Between us there is a gulf fixed of which we are aware only in unquiet moments." Now a much less orthodox, but not Freudian, writer in another Continental journal has recently tried to interpret the symbolism in the familiar story of Samson. It is, he says, a story of a rude, primitive time, containing little of morality, and turning on the three motives of strength, love, and rustic wit. To trace the second motive he has recourse to the sexual symbolism undoubtedly present in the narrative; and when he recalls how the Romans at the Cerealia let loose in the circus foxes with firebrands at their tails, and the rite at Carseoli of covering foxes with grass, setting fire to them, and letting them run over the fields, the fox being regarded as the Genius of the Crops, and kindred Arabian and Japanese rites, it at least puts one strongly in mind of the way in which early civilisations connected phallic symbols with the earth's fertility. Exegesis of this kind will be allowed much significance; and not only this, but also some of the simpler interpretations of sexual symbolism in dreams and neuroses. But with more highly developed ones a feeling of dubiety begins. One perceives that the logical razor of Occam, never very sharp in Austro-Germany, would make short work of many of them. And that, then, is the danger, that sexual symbolism is a risky business. You never know how far to trust it, how far to go with it.

Mr. Havelock Ellis, perhaps the rarest mind in the British medical profession, further pronounces Freud to be an artist. Certainly he is one of the few who are at home either in the literary or the scientific camp, two positions between which there has been small, but for various reasons must in the future be more, communication. It is a bold thing, however, to say that the artistic imagination can serve the purpose of scientific investigation, and a statement unwarranted by history. What might be nearer the truth is that Freud has the specific faculty of the great investigator, the gift of "superb guessing" (which, after all, is essentially reconstructive, not creative), but has it in exuberant degree; like, for instance, Kepler the astronomer. Of his amazing reconstructions of the infant mind he offers hardly a trace of verification. The length of his inductive leaping pole is dangerous, but the reach of his theories impressive. And if it be true that he has opened a new window giving upon the wonderland of the human mind, then it is not fitting to complain of the view.—I am, Sir, yours faithfully,

Sept. 15th, 1919.

CADUCEUS.

## Obituary.

JOHN CAHILL, M.D. DURH., F.R.C.S. ENG.

Dr. John Cahill, whose death on Saturday, Sept. 6th, was alluded to in *THE LANCET* last week, was the only son of the late Dr. Thomas Cahill, of Albert Gate, Knightsbridge. A Catholic, he was born in 1857 and educated at Beaumont College, and then for two years in Germany. He joined the medical school of St. George's Hospital in 1877, but in the year of his qualification as M.R.C.S.—namely, in 1881—his father died. Cahill remained at the hospital discharging the junior appointments, and took the F.R.C.S. Eng. in 1884, when he decided to go into private practice in the neighbourhood where his father and his family were still well remembered. This he did, and for over 30 years he practised in Seville-street, Lowndes-square, his success being alike due to his high professional attainments and his kind and cultivated personality. At first his practice was distinctly surgical, and for some years he was surgeon to the Hospital of St. John and St. Elizabeth, but later he proceeded to the M.D. Durham, and confined himself to general practice. He was medical adviser to the Egyptian Civil Service and a member of the Egyptian Government Medical Commissioners Board, his knowledge of French and German standing him in good stead in such appointments.

Cahill always took a deep interest in the organisation and material prospects of St. George's Hospital, which to him was, of course, not only his old educational centre, but an important local institution. The perplexities which have beset the hospital in the midst of the various rumours with regard to the sale of the site were under discussion by the committee of management of the charity at a time when he was a member of the committee, and on that body no one's voice was more readily heard, both on domestic matters and larger schemes. During the shortage of the medical staff, caused by the calling up of all available men to serve with the forces, Cahill did arduous and unselfish work as temporary assistant physician to the hospital, and his death from heart disease, while still in middle age, can undoubtedly be referred to the strain of professional overwork aggravated by deep sorrow caused by the death of his son.

In 1887 he married Lucy Keith, youngest daughter of the late Thomas Keith, C.B., Accountant General at the India Office, and had two daughters who survive him, as well as an only son, Captain Archibald Cahill, M.C., of the Royal Berkshire Regiment, who was killed in action in 1917. For 40 years Cahill was a well-known man to all connected with St. George's Hospital, and he leaves behind him a reputation for accomplishment, industry, and courtesy which all might envy.

RICHARD FRANCIS TOBIN, F.R.C.S.I.,

PAST PRESIDENT OF THE IRISH MEDICAL ASSOCIATION.

Mr. Richard F. Tobin, of Dublin, died suddenly at his club on August 31st at the age of 76 years. A native of Waterford, he was educated at Clongowes Wood College and Dublin, and after obtaining his licence from the Royal College of Surgeons of Ireland in 1864 at the age of 21 he entered the Army Medical Service. He had a distinguished career, and in 1880 was appointed assistant professor of surgery in the Army Medical School. In 1885 he took part in the Sowakin Expedition, subsequently contributing an account of his experiences to the Transactions of the Royal Academy of Medicine in Ireland. He retired from the Army Medical Service soon afterwards with the rank of Brigade Surgeon, and, settling in Dublin, was appointed a surgeon to St. Vincent's Hospital. He held this post until a few years ago, and earned the reputation of a sound and careful surgeon, taking a special interest in diseases of the prostate. In later years he suffered much from deafness, and some three years ago he retired from active work. He continued, however, to hold the posts of Inspector of Anatomy in Ireland and secretary of the Board of Superintendence of Dublin Hospitals. He was for a time President of the Irish Medical Association, and was surgeon to the Marquis of Aberdeen during the period of his viceroyalty. He wrote a "Synopsis of Surgery," and contributed many articles to the professional journals.

Tobin lost his only son in the Dardanelles, and the grief for this loss, together with his own personal affliction of deafness, would have embittered many men, but with him sorrow only brought out more strongly his native kindness. A few months after his son's death it fell to Tobin's lot to minister professionally to the wounds of James Connolly, the rebel leader of Easter week, in the interval between his surrender and his execution. A friendship sprang up between the two men so curiously unlike—the aristocrat and the revolutionary, the loyal veteran soldier and the avowed rebel. After Connolly's death Tobin made himself, it is believed, responsible for the expense of educating the labour leader's son. The incident is illustrative of the gentleness, the simplicity, and the Christianity of Tobin. He brought the same gentleness and charming courtesy into every relation of life, and no surgeon in Ireland enjoyed more fully the love and friendship of his students and professional colleagues.

## Medical News.

**NATIONAL HOSPITAL FOR DISEASES OF THE HEART, WESTMORELAND-STREET, W.**—Systematic courses of instruction are given from time to time in morbid anatomy, pathology, diagnosis, and treatment of diseases of the heart and circulation. Practical instruction in electrocardiography and graphic methods is also given. Post-graduate students are admitted to the clinical practice of the outpatient department and wards, and application should be made to Captain R. G. E. Whitney, the secretary of the hospital.

**THE War Office** has addressed to Sir Arthur Stanley, the chairman, Joint War Committee, British Red Cross Society and Order of St. John, a letter conveying the appreciation of the Army Council of the inestimable service rendered by the British Red Cross Society and the Order of St. John of Jerusalem in England. In this letter the Council recognise the high value of the work done by the organisations and the hospitals formed under their auspices. "The preparations," they say, "made in time of peace, and the energy and efficiency displayed when put to the test of war, have greatly assisted in the restoration of life and health to the sick and wounded, and have contributed in no small measure to the achievement of victory." Sir Arthur Stanley is finally requested to convey the thanks of the Army Council to the various branches of the two organisations whose members have unstintingly devoted their resources to the services of the sick and wounded.

**BOATING ACCIDENT ON BELFAST LOUGH.**—The bodies of the three victims of the boating accident of August 29th have now been recovered. Mr. Thomas Huston, L.R.C.P. & S. Edin., aged 48, of Woodville House, Hounslow, London, his 12-year-old son, and Mr. Frank Huston, son of Dr. James Huston, Carrickfergus, a medical student, started for a sail on Belfast Lough, nothing more being heard of them until the boat was seen drifting empty. In the course of the last week the bodies were found floating at sea and an inquest followed.

**PRESENTATION.**—The governors of the Royal Devon and Exeter Hospital recently presented Mr. E. J. Domville, consulting surgeon to the charity, with a grandfather clock and an illuminated address, as a mark of appreciation for his services in performing the duties of resident house surgeon for a period of three and a half years during the period of the late war.

**BRISTOL ROYAL INFIRMARY.**—A strong appeal is being made for increased financial support for the Bristol Royal Infirmary. The deficit is £22,170. The president, Mr. H. H. Wills, has offered £5000 conditionally upon the adverse balance being cleared off by the end of the year.

**Messrs. Henry Frowde and Hodder and Stoughton** have in preparation a "Practice of Medicine in the Tropics" by many eminent authorities, edited by Dr. W. Byam and Dr. R. G. Archibald, Majors, R.A.M.C. The number of contributors is 75, drawn from many parts of the world.

**DONATIONS AND BEQUESTS.**—The late Mr. Robert Anderson, of Glasgow, has bequeathed £1000 each to the Glasgow Royal Infirmary, the Western Infirmary, the Glasgow Samaritan Hospital for Women, and the Royal Hospital for Sick Children; and £500 each to the Victoria Infirmary and the Orphan Homes of Scotland.—By the will of the late Mrs. Sarah Finnie, of Kilmarnock, the testatrix left £1000 each to the Zenana Mission of the Church of Scotland and to the Kilmarnock Infirmary, and £350 to the Kilmarnock Nursing Association.

**GUY'S HOSPITAL BIENNIAL DINNER.**—The Guy's biennial dinner will take place at the Connaught Rooms on Tuesday, Oct. 28th, at 7 P.M., Dr. Lauriston Shaw in the chair. All Guy's men who have not received an invitation to the dinner are asked to communicate with Mr. F. J. Steward, 98, Portland-place, London, W. 1.

**UNIVERSITY COLLEGE HOSPITAL.**—The old students' dinner will be held at the Imperial Restaurant, Regent-street, on Friday, Oct. 3rd, Sir J. Rose Bradford in the chair. Tickets 15s. (exclusive of wine) may be obtained from the honorary secretary, Dr. A. M. H. Gray, 30, New Cavendish-street, W. 1.

It has been decided to erect and partially endow a cottage hospital for Helston (Cornwall) as a war memorial. The cost of the scheme is estimated at £4000, and the building will contain eight beds. About £1600 has been subscribed, and it is thought that the amount required will be easily obtained.

**THE Local Government Board** has published what is to all intents and purposes a directory of maternity and infant-welfare centres in England and Wales. The list includes all the municipal and voluntary maternity and child-welfare centres known to the Board on April 1st, 1919. The names and addresses of the secretaries of voluntary centres are also given, and appended is an index of the towns and villages containing centres. It is a most useful little book of reference for all who are engaged in this class of work, but from the point of view of the doctor it would be still more useful were it to contain as well the name of the medical officer who is in charge of each centre. Such a directory would prove of immense help, and we believe that one containing this information has not as yet been published. The Local Government Board list can be procured through any bookseller or from H.M. Stationery Office under the title, "Maternity and Child-Welfare Centres in England and Wales."

**ISOLATION ACCOMMODATION IN NORTH DEVON.**—The question of isolation accommodation has again arisen in North Devon. Dr. W. A. Valentine, medical officer of health for Barnstaple Port Sanitary Authority, reported on Sept. 13th last, at their meeting in Barnstaple, that he had visited the hospital ship with Dr. H. A. Macewen, from the Ministry of Health, and that they found the ship was no longer suitable for the reception of patients. It was suggested by some of the members that a couple of Army huts should be obtained and placed between Instow and Fremington. At a subsequent meeting of the Barnstaple rural council a letter was read from the Lynton urban council stating that the latter were willing to join in a scheme with neighbouring authorities for the provision of an isolation hospital. The chairman, Mr. W. T. Buckingham, said that their chief difficulty lay in the absence of power to remove patients to hospital. They had cases and carriers of diphtheria in the district with whom they could not deal. He pointed out the function of a hospital in the prevention of epidemics. The hospital ship had prevented the spread of small-pox in Appledore when two cases occurred there 20 years ago.

**POST-GRADUATE STUDY IN FRENCH: OPPORTUNITY AT LAVAL.**—Speaking at the recent meeting of the Canadian Medical Association, Professor S. Grondin, of Laval University, Quebec, stated that his university would be glad to receive, free of charge, any young English-speaking doctors of the Dominion who, having passed their degree in their own universities, would like to come to Quebec and follow during one year the lectures given at the university and the clinics in the hospitals. They would, he said, receive a hearty welcome, and after six months would have learned how to speak French. Laval was asking in return from the English universities the same privilege for its young French doctors. Professor Grondin went on to recall his own stay of six months in the Rotunda Hospital at Dublin, ascribing thereto his ability to deliver an address in English. We have no doubt that the Laval offer would be extended to medical graduates from this country who desired to acquire a working knowledge of medical French within the borders of a university of the Empire.

### BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, London.

Handbook of Gynaecology. By Bethel Solomons, M.D. Pp. xii. + 236 10s. 6d.

FROWDE, H., AND HODDER AND STUGHTON, London.

Fractured Femurs. By M. G. Pearson, M.B., B.Sc., and J. Drummond, M.D. Pp. 92. 10s. 6d.

KIMPTON, HENRY, London.

The Operations of Obstetrics. By F. E. Leavitt, M.D. Pp. 466. 30s. A Stereoscopic Atlas of Plastic Surgery of the Face, Head, and Neck, with Case Reports. By J. C. Beck, M.D., and I. Frank. With Stereoscope. 35s.

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

- ADAMS, J., has been appointed Certifying Surgeon under the Factory and Workshop Acts at Bishop's Castle.  
 CAMPBELL, A. S., Certifying Surgeon under the Factory and Workshop Acts at Dundee.  
 CHUBB, ELSIE M., M.D. Lond., D.P.H., Government Medical Inspector of Schools in the Cape Province, South Africa.  
 DAVIS, HARRY, M.R.C.S., L.R.C.P., L.S.A., D.P.H. Camb., Medical Officer for the No. 7 District by the Liskeard (Cornwall) Board of Guardians.  
 FITZGERALD, CHARLES CONWAY, L.R.C.P. & S. Edin., Chief Tuberculosis Officer for the county of Antrim.  
 LANGRAM, WILLIAM, L.R.C.S., L.M. Edin., L.A.H. Dub., Temporary District Medical Officer by the Axminster (Devon) Rural District Council.  
 MCKENNA, T. H., Medical Officer of the Forkhill Dispensary District.

## Vacancies.

For further information refer to the advertisement columns.

- Barbados General Hospital.—Sen. Res. S. £300.  
 Battersea General Hospital, Battersea Park, S.W.—Res. M.O. £200.  
 Bedford County Hospital.—Res. M.O. £150.  
 Belgrave Hospital for Children, Clapham-road, S.W.—Two Asst. P.'s  
 Bermundsey Infirmary, Lower-road, Rotherhithe, S.E.—First Asst. M.O. £350.  
 Bethlehem Royal Hospital, Lambeth-road, S.E.—Hon. Neurologist. Also Jun. Asst. P. £350.  
 Birkenhead Borough Hospital.—Jun. H.S. £170.  
 Birmingham, Lodge-road War Pensioners Hospital.—Asst. M.O. £350.  
 Birmingham Municipal Anti-Tuberculosis Centre.—Sen. Asst. Tuberc. O. £650.  
 Bridge of Weir, near Glasgow, Consumption Sanatoria of Scotland.—Asst. M.O. £200.  
 Brighton, Royal Sussex County Hospital.—Asst. H.S. £80.  
 Cardiff, King Edward VII.'s Hospital.—H.S. £200.  
 Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—H.S. £50.  
 Cheltenham Eye, Ear, and Throat Free Hospital.—Asst. S. £400.  
 Chester, Cheshire County Council.—Dist. Tuberc. O. £400.  
 Crowthorne, Berks, Broadmoor State Asylum.—Asst. M.O. £300-£350.  
 Cumberland Education Committee.—Two School Dentists. £350.

 Whitehaven and West Cumberland Infirmary.—Res. H.S. £180.  
 Wolverhampton and Staffordshire General Hospital.—H.S. £200.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Malton (York).

## Births, Marriages, and Deaths.

### BIRTHS.

- BRIMBLECOMBE.—On Sept. 10th, at Willow Bank, Martock, Somerset, the wife of S. L. Brimblecombe, M.R.C.S., L.R.C.P., of a son.  
 DENT.—On Sept. 9th, at 21, Endsleigh-street, to Lieutenant R. W. Dent, H.M.T.S. *Monarch*, and Dr. Patricia Dent (née Barnes), of Okeburn, Ambleside Avenue, Streatham, a daughter.  
 DOLL.—On Sept. 8th, at Hill-street, Knightsbridge, the wife of Dr. H. William Doll, of a son.  
 ORAM.—On Sept. 11th, at St. Michael's Lodge, Deepcut, Farnborough, Hants, the wife of Captain A. R. Oram, M.C., R.A.M.C., of a son (Richard).

### MARRIAGES.

- BROUGHTON-HEAD-BLAND.—On Sept. 10th, at Christ Church, Brondesbury Park, London, N.W., Leslie Charles Broughton-Head, M.B., L.D.S. Eng., to Dorothy, elder daughter of George R. Bland, Brondesbury Park, N.W.  
 CONNAN-MACKINTOSH.—On Sept. 11th, at Trinity Presbyterian Church, Donald Murray Connan, M.B., B.S., to Annie Dorothy, second daughter of Rev. Eneas and Mrs. Mackintosh, of Temuka, Alton, Hants.  
 HARVEY-DOHERTY.—On Sept. 15th, 1919, at St. Pancras Parish Church, London, by the Vicar, Rev. E. L. Metcalfe, M.A., and the Rev. E. Harvey, M.A., brother of the bridegroom, Joseph Harvey, Captain, R.A.M.C. (T.C.), youngest son of the late Mr. John Harvey and Mrs. Harvey, Rathmines, Dublin, to Winifred Eleanor, fifth daughter of Mr. and Mrs. W. Doherty, Claremont, Western Australia.  
 STEILL-HOLLAND.—On Sept. 15th, at Nettleham Parish Church, Lincoln, by the Rev. C. K. Watkins, William Fletcher Stiell, M.R.C.S., L.R.C.P., youngest son of Dr. and Mrs. Stiell, of Clapham, London, S.W., to Margaret, younger daughter of Mr. George Holland and the late Mrs. Holland, of "Kelvin," Lime Tree Avenue, Retford.  
 WRIGHT-DEAN.—On Sept. 9th, at Metheringham, Charles Samue Eric Wright, M.B., to Kathleen Mary, only daughter of Mr. and Mrs. J. H. Dean, Heath House, Nocton, Lincoln.

### DEATHS.

- ECCLES.—On Sept. 9th, at Upper Norwood, William Soltan Eccles, M.R.C.S. Eng., aged 76 years.  
 MACNAB.—On Sept. 12th, at Lansdown-place East, Bath, Robert Macnab, M.D. Glasg., F.R.C.S. Edin., aged 78 years.  
 MEEK.—On Sept. 15th, suddenly, at Frimley, Wilfrid Ombler Meek, M.B., B.S. Lond., in his 40th year.  
 RASKIN.—On Sept. 14th, at The Orchard, Helford, Corawall, Gathrie Rankin, M.D., F.R.C.P., and of 9, Harley street, London.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

# Medical Diary for the ensuing Week.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Special Course of Instruction in the Surgical Dyspepsias will be given by Mr. A. J. Walton:—

MONDAY, Sept. 22nd.—4.30 P.M., Lecture XV.:—Foreign Bodies, Rupture of the Stomach, Gastric Adhesions, Acute Dilatation of the Stomach.

FRIDAY.—4.30 P.M., Lecture XVI.:—Technique and Complications of Gastric Operations.

# Notes, Short Comments, and Answers to Correspondents.

## THE ECONOMICS OF NIGHT CALLS.

It was recently recorded in the obituary notice of a well-known north-country practitioner that throughout his long and active professional life he was able to attend to a series of night calls without deterioration of his day-time work. This ability must surely be passing with the brave age of heroes. The present-day practitioner is of commoner clay, and there must be few who do not experience some loss of attention or of interest in their work after a bite out of the night's sleep. The matter has its bearing, too, from the patient's point of view; a jaded doctor, even if, as we are assuming here, his night-watching is the result of professional engagements, is not worth as much as a fresh one. The Federation of Ratepayers Associations at Johannesburg recently discussed the question, debating whether suitable provision could not be made for procuring medical attention and medicines during the night time. Dr. E. P. Baumann, senior physician to the Johannesburg Hospital, attended by invitation to submit the point of view of medical practitioners. He urged that though the question of fees was a consideration it was not the primary one, and he suggested that some steps be taken to form a panel of junior practitioners to whom night work would be a welcome introduction to the public. His estimate that 99.9 per cent. of night calls were futile and not cases of necessity may have been intentionally picturesque, but he went on very justly to point out the physical strain of night calls upon a practitioner who had spent a busy day. A subcommittee was appointed to discuss the question with the local medical profession and to report to the Federation. Something instructive may come of it.

## "STAMMERING AND VOICE DEFECTS."

To the Editor of THE LANCET.

SIR,—With reference to Miss Emil Behnke's comment on the statement I made in my paper on the above subject in your issue of August 23rd, may I say that I think my meaning was rather misunderstood.

I know the late Mrs. Behnke's books on the subject well, and have in the past obtained valuable help from them. By saying that "stammering and functional voice defects have until recently been looked upon as unfortunate disabilities, and no real scientific attempt was made thoroughly to deal with such cases, and hence there was no recognised cure," I mean that stammering and functional voice defects have not until recently been regarded as an evidence of a disease which required specialised medical treatment in addition to specialised speech treatment. As a rule, stammering, &c., patients were sent to teachers of elocution or speech specialists—the cure being left to them entirely—and the symptom alone was treated. Now, however, it is generally accepted that the symptom—i.e., stammering, &c.—cannot permanently be cured until the underlying psychic cause has been dealt with, and this latter can only successfully be accomplished by those trained in psychological medicine. My paper, of course, only referred to functional and not to organic voice defects.

I am, Sir, yours faithfully,

Blackheath, S.E., Sept. 10th, 1919.

MABEL V. O. OSWALD.

## COLONIAL HEALTH REPORTS.

Basutoland.—The report on this territory for 1917-18 states that typhus fever, which had been prevalent for more than a year in certain districts of Cape Colony, appeared in August, 1917. The early cases were nearly all among the Tembu of the Quthing and Mohales Hoek districts. Later, cases occurred in the Qacha's Nek district. Energetic measures were at once taken to control the epidemic. Infected areas were strictly quarantined. Recruiting for mines and other purposes was prohibited in the southern districts and every means taken to discourage the movements of natives from one place to another. All infected huts were destroyed by fire, and clothing and other personal effects disinfected by boiling. The death-rate was high—about 50 per cent.—but this resulted in the people, who were thoroughly scared, co-operating actively with the authorities in enforcing quarantines. This would not have been the case had the disease been attended with a low mortality. From August 14th, when the first cases were noted, till Dec. 31st, there were 215 cases with 100 deaths. No Europeans were affected. There was no case of small-pox. A good many men suffering from malarial fever came under the notice of the medical officers.

They were all imported cases, chiefly returned general service boys from German East Africa. Syphilis is still very prevalent, and a proposal is under consideration to inaugurate free treatment for the disease. The general difficulty in dealing with the problem of syphilis in a native territory is the indifference of the people. Most cases have a non-venereal origin (only 16 cases of chancre were seen during the year); the initial lesion is often overlooked, mucous patches on the mouth follow, and the infection spreads from one member of a family to another, and whole villages may be rapidly infected. In a great many instances the secondary symptoms subside without treatment, but not before the patient has passed infection on to many others. Dysentery was again prevalent, but much milder in type than in recent years. There were a few cases of meningitis, mostly tubercular in origin. The general health of the community has been above the average. 1997 in-patients and 32,347 out-patients were treated at the Government hospitals and dispensaries. On April 1st, 1917, there were 181 male and 182 female inmates of the Leper Asylum, and during the year ended March 31st, 1918, 52 new cases were admitted. One patient was discharged as a possibly arrested case; there were 29 deaths and 8 births. Of 43 deserters all but two returned to the settlements. There has been an improvement in the general health of the inmates.

*Nyasaland.*—In 1917-18 the health of the Protectorate was not satisfactory owing to the extensive movement of natives necessitated by the military operations. Small-pox, which in the previous year was confined to the Dowa and Lilongwe districts, made its appearance in seven other areas. It was found impossible to entirely restrict the movements of natives with a view to checking the spread of the disease, as the increasing military demands for labour had to be made. Owing to the lack of medical officers sleeping sickness investigations had to be suspended. Twenty-eight cases of plague were reported from Karonga in the North Nyasa district, the outbreak being merely a continuance of the one reported in the previous year. The extermination of rats, inoculation, and other preventive measures which were adopted not only checked the local spread of the disease, but prevented its gaining an entry into other parts of the Protectorate. As in the case of plague, cerebro-spinal meningitis was introduced into Nyasaland from German East Africa. It was first observed among the native German prisoners of war who were sent to Zomba for internment. Sixty-seven cases were recorded during the year; the case mortality was high, but of the three Europeans who contracted the disease only one died. The number of Europeans resident, including officials and non-officials, but excluding the military, was 463 males and 215 females. The Asiatic population amounted to 422. The native population is estimated at 1,227,442—approximately 559,810 males and 667,632 females.

#### NOCTURNAL ENURESIS.

To the Editor of THE LANCET.

SIR,—Can any of your readers suggest treatment for a boy, aged 9, who suffers from incontinence of urine both by day and night? By constant supervision—telling him to pass water every two hours or so—he can be kept dry. He apparently has no "call" when the bladder is full, as he has been known to declare that he did not wish to pass water during the very act of micturition, he not being aware of the fact that he was passing water. He is a well-nourished and apparently healthy boy except that he is a had stammerer.

I am, Sir, yours faithfully,

9, Welbeck-street, Cavendish-square, W. 1,  
Sept. 10th, 1919.

F. ST. J. S.

#### OCULIST AND OPTICIAN.

THE following letter, signed "F.," appears in the *Times* of Sept. 10th:—

"Even more important than opticians' prices is the verification of opticians' work. My oculist ordered me a change of lenses. I took the prescription to an optician of repute, recommended by my oculist, but the new glasses, luckily for me, pained my eyes, and I went back to the oculist. He found, to his intense indignation, that the prescription had been incorrectly carried out. The optician made the usual excuse of war conditions, and later had the impudence to send me an additional bill for putting the glasses right, which of course I flatly refused to pay. There should be a regular system of verification. Without it the skill of the oculist may be all in vain, and the patient's eyes may suffer irreparable injury. It would be a little more trouble for the oculist to see his patient again, but he would sometimes be as surprised and indignant as my friend was."

We have had occasion to point out that the work of the ophthalmologist may be entirely disorganised by a lack of conscience or knowledge on the part of the optician, adding that in our experience most opticians do their work, as such, extremely well. The real message to the public contained in "F.'s" letter is that it is dangerous to resort to the optician for a prescription for glasses. In "F.'s" case, by falling back on the qualified ophthalmologist, the source of his trouble was detected. A rejoinder to "F.'s" letter appeared on the

following day in which the pertinent warning is given that some opticians are not to be trusted, though others are excellent scientific workers.

#### THE SURGEON AND HIS FAMILY.

THE *patria potestas* was accurately defined by the Roman Code, but in modern civilisation the duties and privileges of the father of the family towards his own household are determined rather by broad views of equity and by the force of accumulated public opinion than by statute. Many of these duties are common to all ranks of society and to all kinds of occupation, but there are special privileges attaching to fathers who possess special qualifications. The schoolmaster helps his son at home with his school lessons; the hoo-maker patches the shoes which otherwise go out to be done; the public hygienist exerts in his private family that special supervision in the prevention of disease for which his larger experience qualifies him. It would be absurd to exclude the surgeon from the position of special helpfulness to his own household. The question has been recently discussed in the daily press in the light of a tragic incident. The scanty story relates to a man who, after receiving serious injuries in a shooting accident, was taken to a county hospital where his father, a consulting surgeon, performed an operation upon him, but was unable to save his son's life. No details were given in regard to the urgency of surgical intervention nor what opportunity of assistance or consultation were open to the surgeon. But on general grounds the propriety of a father operating upon his son has been apparently called in question. The argument seems to rest upon the assumption that a surgeon in the position of a near relative cannot offer to his patient the same skill which he could give to a stranger. It overlooks the fact that the whole course of medical training is directed towards transforming the emotion of pity into the instinct of helpfulness. Were this mutation incomplete no medical man would trust himself to be arbiter of human life at all. To the surgeon his art has no affective tone. Blood is simply a corpuscular fluid with certain chemical and physical properties. Small casualties occurring in the house of the medical practitioner are, of course, dealt with as a matter of ordinary routine, the more so probably as the medical man suffers under the disability of not being allowed, in most instances, to pay the colleague whom he calls in. On this account, as well as for convenience, the practitioner frequently gives the anaesthetic to any member of his family when a larger surgical intervention is needed. What is to be regarded as a major operation depends on the skill of the surgeon. In a report recently received from a hospital in India paracentesis abdominis and curettage are classed as such. The hospital surgeon in this country possesses the skill which makes the so-called major operation to him an ordinary everyday task. To deprive him of the privilege of offering his services to members of his family in urgent need would be stupid; his call is often no less clear than that of Abraham to use the knife on his own son.

#### A TAR-SPRAYING FATALITY.

THE death is reported from pustular dermatitis of a labourer employed in tar-spraying the road. It is stated that some of the tar spray came into contact with his face and neck. Inflammatory conditions of the skin have been known to he set up amongst the workers engaged on moulding pitch into "patent fuel," and pitch, of course, is related to tar. "Pitch cancer" was a matter of inquiry by the Home Office some years ago, and certain protective measures were recommended which the manufacturers agreed to adopt (vide THE LANCET, Sept. 6th, 1913). It seems desirable that similar precautions should be taken by tar-pavers, particularly as the process is conducted on a very large scale on our roadways.

#### RHEUMATOID ARTHRITIS OF THE SPINE.

Spes writes:—I have a patient who suffers severe pain which I can only relieve by morphia injections—everything else tried has failed to alleviate. Can anyone who has had similar cases give me any help by suggestions?

J. B. D.—It is usual in cities (and a commendable practice) to carry out the work of cleaning and tidying the streets in the small hours of the morning when the traffic is at its lowest.

Temp. Major.—Temporary officers of the Royal Army Medical Corps are not entitled to any gratuity on demobilisation other than the bonus of £60 a year granted to them under the terms of their contract, except in the case of those who have for a period of six months or longer held acting rank higher than that of Captain, and have drawn the Army pay and allowances of the higher rank, in which case they are awarded the gratuity equal to that allowed under Article 497 of the Royal Warrant, less any gratuity which may have already been drawn under the provisions as set forth in the contract for the award of £60 on completion of each year's service.

# Presidential Address

ON

## THE DIFFERENTIATION OF MANKIND INTO RACIAL TYPES.

*Delivered before the Anthropological Section of the British Association for the Advancement of Science*

BY PROF. ARTHUR KEITH, M.D. ABERD.,  
LL.D., F.R.S.,

HUNTERIAN PROFESSOR AND CONSERVATOR OF THE MUSEUM, ROYAL  
COLLEGE OF SURGEONS OF ENGLAND.

LADIES AND GENTLEMEN,—For a brief half-hour I am to try and engage your attention on a matter which has excited the interest of thoughtful minds from ancient times—the problem of how mankind has been demarcated into types so diverse as the Negro, the Mongol, and the Caucasian or European.

### EXPLANATIONS, ANCIENT AND MODERN.

For many a day the Mosaic explanation—the tower of Babel theory—was regarded as a sufficient solution of this difficult problem. In these times most of us have adopted an explanation which differs in many respects from that put forward in the book of Genesis; Noah disappears from our theory and is replaced in the dim distance of time by a “common ancestral stock.”

Our story now commences, not at the close of a historical flood, but at the end of a geological epoch so distant from us that we cannot compute its date with any degree of accuracy. Shem, Ham, and Japheth, the reputed ancestors of the three great racial stocks of modern times—the white, black, and yellow distinctive types of mankind—have also disappeared from our speculations; we no longer look out on the world and believe that the patterns which stud the variegated carpet of humanity were all woven at the same time; some of the patterns, we believe, are of ancient date and have retained many of the features which marked the “common ancestral” design; others are of more recent date, having the ancient pattern altered in many of its details.

We have called in, as Darwin has taught us, the whole machinery of evolution—struggle for existence, survival of the fittest, spontaneous origin of structural variations, the inheritance of such variations—as the loom by which Nature fashions her biological patterns. We have replaced the creative finger by the evolutionary machine, but no one is more conscious of the limitations of that machine than the student of human races.

We are all familiar with the features of that racial human type which clusters round the heart of Africa; we recognise the Negro at a glance by his black, shining, hairless skin, his crisp hair, his flattened nose, his widely opened dark eyes, his heavily moulded lips, his gleaming teeth and strong jaws. He has a carriage and proportion of body of his own; he has his peculiar quality of voice and action of brain. He is, even to the unpractised eye, clearly different from the Mongolian native of North-Eastern Asia; the skin, the hair, the eyes, the quality of brain and voice, the carriage of body and proportion of limb to body pick out the Mongol as a sharply differentiated human type. Different from either of these is the native of Central Europe—the Aryan or Caucasian type of man; we know him by the paleness of his skin and by his facial features—particularly his narrow, prominent nose and thin lips. We are so accustomed to the prominence of the Caucasian nose that only a Mongol or Negro can appreciate its singularity in our aryanised world. When we ask how these three types—the European, Chinaman, and Negro—came by their distinctive features, we find that our evolutionary machine is defective; the processes of natural and of sexual selection will preserve and exaggerate traits of body and of mind, but they cannot produce that complex of features which marks off one racial type from another. Nature has at her command some secret mechanism by which she works out her new patterns in the bodies of man and beast—a mechanism of which we were almost ignorant in Darwin's day, but which we are now beginning to perceive and dimly understand. It is the bearing of this creative or morphogenetic mechanism on the evolution of the modern races of mankind which I propose to make the subject of my address.

No. 5013

### THE ENDOCRINE GLANDS AS GROWTH-CONTROLLING STRUCTURES.

Hidden away in various parts of the human frame is a series of more or less obscure bodies or glands, five in number, which, in recent times, we have come to recognise as parts of the machinery which regulate the growth of the body. They form merely a fraction of the body—not more than 1/180th part of it; a man might pack the entire series in his watch-pocket. The modern medical student is familiar with each one of them—the pituitary body, about the size of a ripe cherry, attached to the base of the brain and cradled in the floor of the skull; the pineal gland, also situated in the brain, and in point of size but little larger than a wheat-grain; the thyroid in the neck, set astride the windpipe, forms a more bulky mass; the two suprarenal bodies situated in the belly, capping the kidneys, and the interstitial glands embedded within the substance of the testicle and ovary, complete the list. The modern physician is also familiar with the fact that the growth of the body may be retarded, accelerated, or completely altered if one or more of these glands become the seat of injury or of a functional disorder.

### Acromegaly and Giantism.

It is 33 years now since first one woman and then another came to Dr. Pierre Marie in Paris seeking relief from a persistent headache, and mentioning incidentally that their faces, bodies, hands, and feet had altered so much in recent years that their best known friends failed to recognise them. That incident marked the commencement of our knowledge of the pituitary gland as an intrinsic part of the machinery which regulates the shaping of our bodies and features. Dr. Marie named the condition acromegaly. Since then hundreds of men and women showing symptoms similar to those of Dr. Marie's patients have been seen and diagnosed, and in every instance where the acromegalic changes were typical and marked there has been found a definite enlargement or tumour of the pituitary body. The practised eye recognises the full-blown condition of acromegaly at a glance, so characteristic are the features of the sufferers. Nay, as we walk along the streets we can note slight degrees of it—degrees which fall far short of the border-line of disease; we note that it may give characteristic traits to a whole family—a family marked by what may be named an acromegalic taint.

The pituitary gland is also concerned in another disturbance of growth—giantism. In every case where a young lad has shot up, during his late “teens,” into a lanky man of seven feet or more—has become a giant—it has been found that his pituitary gland was the site of a disordered enlargement. The pituitary is part of the mechanism which regulates our stature, and stature is a racial characteristic. The giant is usually acromegalic as well as tall, but the two conditions need not be combined; a young lad may undergo the bodily changes which characterise acromegaly and yet not become abnormally tall, or he may become—although this is rarely the case—a giant in stature and yet may not assume acromegalic features.

There is a third condition of disordered growth in which the pituitary is concerned—one in which the length of the limbs is disproportionately increased—in which the sexual system and all the secondary sexual characters of body and mind either fail to develop or disappear—where fat tends to be deposited on the body, particularly over the buttocks and thighs—where, in brief, a eunuchoid condition of body develops.

In all of these three conditions we seem to be dealing with a disordered and exaggerated action of the pituitary gland; there must be conditions of an opposite kind where the functions of the pituitary are disordered and reduced. A number of cases of dwarfism have been recorded where boys or girls retained their boyhood or girlhood throughout life, apparently because their pituitary gland had been invaded and partly destroyed by tumours. We shall see that dwarfism may result also from a failure of the thyroid gland. On the evidence at our disposal, evidence which is being rapidly augmented, we are justified in regarding the pituitary gland as one of the principal pinions in the machinery which regulates the growth of the human body and is directly concerned in determining stature, cast of features, texture of skin, and character of hair—all of them marks of race. When we compare the three chief racial types of humanity—the Negro, the Mongol, and the Caucasian or European—we can recognise in the last named a greater predominance

of the pituitary than in the other two. The sharp and pronounced nasalisation of the face, the tendency to strong eyebrow ridges, the prominent chin, the tendency to bulk of body and height of stature in the majority of Europeans, are best explained, so far as the present state of our knowledge goes, in terms of pituitary function.

#### *The Genital Glands in Relation to Growth.*

There is no question that our interest in the mechanism of growth has been quickened in recent years by observations and discoveries made by physicians on men and women who suffered from pituitary disorders, but that a small part of the body could influence and regulate the growth and characterisation of the whole was known in ancient times. For many centuries it has been common knowledge that the removal of the genital glands alters the external form and internal nature of man and beast. The sooner the operation is performed after birth the more certain are its effects. Were a naturalist from a unisexual world to visit this earth of ours it would be difficult to convince him that a brother and a sister were of the same species, or that the wrinkled, sallow-visaged eunuch with his beardless face, his long tapering limbs, his hesitating carriage, his carping outlook and corpulent body, was brother to the thick-set, robust, pugilistic man with the bearded face.

The discovery that the testicle and ovary contain, scattered throughout their substance, a small glandular element which has nothing to do with their main function—the production of genital cells—was made 70 years ago, but the evidence which leads us to believe that this scattered element—the interstitial gland—is directly concerned in the mechanism of growth is of quite recent date. All those changes which we may observe in the girl or boy at puberty—the phase of growth which brings into full prominence their racial characteristics—depend on the action of the interstitial glands. If they are removed or remain in abeyance the maturation of the body is both prolonged and altered. In seeking for the mechanism which shapes mankind into races we must take the interstitial gland into our reckoning. I am of opinion that the sexual differentiation—the robust manifestations of the male characters—is more emphatic in the Caucasian than in either the Mongol or Negro racial types. In both Mongol and Negro, in their most representative form, we find a beardless face and almost hairless body, and in certain Negro types, especially in Nilotic tribes, with their long, stork-like legs, we seem to have a manifestation of abeyance in the action of the interstitial glands. At the close of sexual life we often see the features of a woman assume a coarser and more masculine appearance.

#### *The Suprarenal Bodies.*

Associated with the interstitial glands, at least in point of development, are the suprarenal bodies or glands. Our knowledge that these two comparatively small structures, no larger than the segments into which a moderately sized orange can be separated, are connected with pigmentation of the skin dates back to 1894, when Dr. Thomas Addison, a physician to Guy's Hospital, London, observed that gradual destruction of these bodies by disease led to a darkening or pigmentation of the patient's skin, besides giving rise to other more severe changes and symptoms. Now it is 150 years since John Hunter came to the conclusion, on the evidence then at his disposal, that the original colour of man's skin was black, and all the knowledge that we have gathered since his time supports the inference he drew. From the fact that pigment begins to collect in and thus darken the skin when the suprarenal bodies become the seat of a destructive disease we infer that they have to do with the clearing away of pigment, and that we Europeans owe the fairness of our skins to some particular virtue resident in the suprarenal bodies.

That their function is complex and multiple the researches of Sharpey-Schafer, of T. R. Elliott, and of W. B. Cannon have made very evident. Fifteen years ago Bulloch and Sequeira established the fact that when a suprarenal body becomes the site of a peculiar form of malignant overgrowth in childhood the body of the boy or girl undergoes certain extraordinary growth changes. The sexual organs became rapidly mature, and through the framework of childhood burst all the features of sexual maturity—the full chest, muscularity of limbs, bass voice, bearded face,

and hairy body—a miniature Hercules—a miracle of transformation in body and brain. Corresponding changes occur in young girls—almost infants in years—with a tendency to assume features which characterise the male. Professor E. E. Glynn<sup>1</sup> has recently collected such cases and systematised our knowledge of these strange derangements of growth.

There can be no doubt that the suprarenal bodies constitute an important part of the mechanism which regulates the development and growth of the human body and helps in determining the racial characters of mankind. We know that certain races come more quickly to sexual maturity than others, and that races vary in development of hair and of pigment, and it is therefore reasonable to expect a satisfactory explanation of these characters when we have come by a more complete knowledge of the suprarenal mechanism.

#### *The Pineal Gland.*

During the last few years the totally unexpected discovery has been sprung upon us that disease of the minute pineal gland of the brain may give rise to a train of symptoms very similar to those which follow tumour formation of the cortex of the suprarenal bodies. In some instances the sudden sexual prematurity which occurs in childhood is apparently the immediate result of a tumour-like affection of the pineal gland. We have hitherto regarded the pineal gland, little bigger than a wheat-grain and buried deeply in the brain, as a mere useless vestige of a median or parietal eye, derived from some distant human ancestor in whom that eye was functional, but on the clinical and experimental evidence now rapidly accumulating we must assign to it a place in the machinery which controls the growth of the body.

#### *The Thyroid Gland.*

We come now to deal with the thyroid gland, which, from an anthropological point of view, must be regarded as the most important of all the organs or glands of internal secretion. Here, too, in connexion with the thyroid gland, which is situated in the front of the neck, where it is so apt to become enlarged and prominent in women—I must call attention to a generalisation which I slipped over when speaking of the pituitary and suprarenal glands. Each of these glands throws into the circulating blood two sets of substances—one set to act immediately in tuning the parts of the body which are not under the influence of the will to the work they have to do when the body is at rest and when it is making an effort. Another set of substances—which Professor Gley has named morphogenetic—has not an immediate but a remote effect; they regulate the development and coördinate the growth of the various parts of the body.

Now, so far as the immediate function of the thyroid is concerned, our present knowledge points to the gland as the manufactory of a substance which, when circulating in the body, regulates the rate of combustion of the tissues. When we make a muscular effort, or when our bodies are exposed to cold, or when we become the subjects of infection, the thyroid is called upon to assist in mobilising all available tissue-fuel. If we consider only its immediate function it is clear that the thyroid is connected with the selection and survival of human races. When, however, we consider its remote or morphogenetic effects on growth its importance as a factor in shaping the characteristics of human races becomes even more evident. In districts where the thyroid is liable to that form of disease known as goitre it has been known for many a year that children who were affected became cretins—dwarf idiots with a very characteristic appearance of face and body.<sup>2</sup>

Disease of the thyroid stunts and alters the growth of the body, so that the subjects of this disorder might well be classed as a separate species of humanity. If the thyroid becomes diseased and defective after growth of the body is completed, then certain changes, first observed by Sir William Gull in 1873, are set up and give rise to the disordered state of the body known as myxœdema. "In this state," says Sir Malcom Morris,<sup>3</sup> "the skin is cold, dry and rough, seldom or never perspires, and may take on a yellowish tint; there is a bright-red flush in the malar

<sup>1</sup> Quart. Journ. of Med., 1912, vol. v., p. 157.

<sup>2</sup> The story of the discovery of the action of the thyroid gland is told by Professor G. M. Murray, Brit. Med. Jour., 1913, ii., 163.

<sup>3</sup> Brit. Med. Jour., 1913, i., 1035.

region. The skin as a whole looks transparent; the hair of the scalp becomes scanty; the pubic and axillary hair, with the eyelashes and eyebrows, often falls out; in many cases the teeth are brittle and carious. All these appearances disappear under the administration of thyroid extract."

We have here conclusive evidence that the thyroid acts directly on the skin and hair, just the structures we employ in the classification of human races. The influence of the thyroid on the development of the other systems of the body, particularly on the growth of the skull and skeleton, is equally profound. This is particularly the case as regards the base of the skull and the nose. The arrest of growth falls mainly on the basal part of the skull, with the result that the root of the nose appears to be flattened and drawn backwards between the eyes, the upper forehead seems projecting or bulging, the face appears flattened, and the bony scaffolding of the nose, particularly when compared to the prominence of the jaws, is greatly reduced.

Now these facial features which I have enumerated give the Mongolian face its characteristic aspect, and, to a lesser degree, they are also to be traced in the features of the Negro. Indeed, in one aberrant branch of the Negro race—the Bushman of South Africa—the thyroid facies is even more emphatically brought out than in the most typical Mongol. You will observe that, in my opinion, the thyroid—or a reduction or alteration in the activity of the thyroid—has been a factor in determining some of the racial characteristics of the Mongol and the Negro races. I know of a telling piece of evidence which supports this thesis. Some years ago there died in the East End of London a Chinese giant—the subject, we must suppose, of an excessive action of the pituitary gland—the gland which I regard as playing a predominant part in shaping the face and bodily form of the European. The skeleton of this giant was prepared and placed in the museum of the London Hospital Medical College by Colonel T. H. Openshaw, and any one inspecting this skeleton can see that, although certain Chinese features are still recognisable, the nasal region and the supra-orbital ridges of the face have assumed the more prominent European type.

#### *Achondroplasia and Mongolism.*

There are two peculiar and very definite forms of dwarfism with which most people are familiar, both of which must be regarded as due to a defect in the growth regulating mechanism of the thyroid. Now, one of these forms of dwarfism is known to medical men as achondroplasia, because the growth of cartilage is particularly affected, but in familiar language we may speak of the sufferers from this disorder of growth as being of the "bulldog breed" or of the "dachshund breed." In the dachshund the limbs are greatly shortened and gnarled, but the nose or snout suffers no reduction, while in the bulldog the nose and nasal part of the face are greatly reduced and withdrawn, showing an exaggerated degree of Mongolism. Among achondroplastic human dwarfs both breeds occur, but the "bulldog" form is much more common than the "dachshund" type. The shortening of limbs with retraction of the nasal region of the face—pug-face or prosopia we may call the condition—has a very direct interest for anthropologists, seeing that short limbs and a long trunk are well-recognised racial characteristics of the Mongol.

In the second kind of dwarfism, which we have reason to regard as due to a functional defect of the thyroid, the Mongolian traits are so apparent that the sufferers from this disorder are known to medical men as "Mongolian idiots," for not only is their growth stunted, but their brains also act in a peculiar and aberrant manner. Dr. Langdon Down, who gave the subjects of this peculiar disorder the name "Mongolian idiots" 55 years ago, knew nothing of the modern doctrine of internal secretions, but that doctrine has been applied in recent years by Dr. F. G. Crookshank<sup>1</sup> to explain the features and condition of Mongoloid imbecile children.

Some years ago<sup>2</sup> I brought forward evidence to show that we could best explain the various forms of anthropoid apes by applying the modern doctrine of a growth-controlling glandular mechanism. In the gorilla we see the effects of a predominance of the pituitary elements; in the orang, of the thyroid. The late Professor Klaatsch tried to account for the superficial resemblances between the Malay and the

orang by postulating a genetic relationship between them; for a similar reason he derived the Negro type from a gorilline ancestry. Occasionally we see a man or woman of supposedly pure European ancestry displaying definite Mongoloid traits in their features.

We have been in the habit of accounting for such manifestations by the theory, at one time very popular, that a Mongoloid race had at one time spread over Europe, and that Mongoloid traits were atavistic recurrences. An examination of the human remains of ancient Europe yields no evidence in support of a Turanian or Mongol invasion of Europe.

#### THE MECHANISM OF THE CONTROL OF GROWTH.

All of these manifestations to which I have been calling your attention—the sporadic manifestation of Mongoloid characters in diseased children and in healthy adult Europeans, the generic characters which separate one kind of ape from another, the bodily and mental features which mark the various races of mankind—are best explained by the theory I am supporting—namely, that the conformation of man and ape and of every vertebrate animal is determined by a common growth-controlling mechanism which is resident in a system of small but complex glandular organs. We must now look somewhat more closely into the manner in which this growth-regulating mechanism actually works.

That we can do best by taking a glimpse of a research carried out by Bayliss and Starling in the opening years of the present century. They were seeking to explain why it was that the pancreas poured out its digestive juice as soon as the contents of the stomach commenced to pass into the first part of the duodenum. It was then known that if acid was applied to the lining epithelial membrane of the duodenum, the pancreas commenced to work; it was known also that the message which set the pancreas into operation was not conveyed from the duodenum to the pancreas by nerves, for when they were cut the mechanism was still effective. Bayliss and Starling solved the puzzle by making an emulsion from the acid-soaked lining epithelium of the duodenum and injecting the extract of that emulsion into the circulating blood. The result was that the pancreas was immediately thrown into activity. The particular substance which was thus set circulating in the blood and acted on the pancreas and on the pancreas alone, and which thus served as a messenger or hormone, they named secretin. They not only cleared up the mechanism of pancreatic secretion, but at the same time made a discovery of much greater importance. They had discovered a new method whereby one part of the human body could communicate with and control another.

#### *The Theory of Hormones.*

Up to that time we had been like an outlandish visitor to a strange city, who believed that the visible telegraph or telephone wires were the only means of communication between its inhabitants. We believed that it was only by nerve fibres that intercommunication was established in the animal body. Bayliss and Starling showed that there was a postal system. Missives posted in the general circulation were duly delivered at their destinations. The manner in which they reached the right address is of particular importance for us; we must suppose that the missive or hormone circulating in the blood and the recipient for which they are intended have a special attraction or affinity for each other—one due to their physical constitution—and hence they, and only they, come together as the blood circulates round the body.

Secretin is a hormone which effects its errand rapidly and immediately, whereas the growth or morphogenetic hormones, thrown into the circulation by the pituitary, pineal, thyroid, suprarenals, and genital glands, act slowly and remotely. But both are alike in this: the result depends not only on the nature of the hormone or missive, but also on the state of the local recipient. The local recipient may be specially greedy, as it were, and seize more than a fair share of the manna in circulation, or it may have "sticky fingers" and seize what is not really intended for local consumption.

We can see that local growth—the development of a particular trait or feature—is dependent not only on the hormones supplied to that part, but also on the condition of the receptive mechanism of the part. Hence we can understand a local derangement of growth—an acromegaly or gigantism confined to a finger or to the eyebrow ridges, to the nose, to one side of the face, and such local manifestations

are not uncommon. It is by a variation in the sensitiveness of the local recipient that we have an explanation of the endless variety to be found in the relative development of racial and individual features.

#### *Regulation of Muscular Effort.*

Some ten years after Starling had formulated the theory of hormones Professor W. B. Cannon, of Harvard University, piecing together the results of researches by Dr. T. R. Elliott and by himself on the action of the suprarenal glands, brought to light a very wonderful hormone mechanism—one which helps us in interpreting the action of growth-regulating hormones. When we are about to make a severe bodily effort it is necessary to flood our muscles with blood, so that they may have at their disposal the materials necessary for work—oxygen and blood-sugar—the fuel of muscular engines.

At the beginning of a muscular effort the suprarenal glands are set going by messages passing to them from the central nervous system; they throw a hormone—adrenalin—into the circulating blood, which has a double effect; adrenalin acts on the flood-gates of the circulation, so that the major supply of blood passes to the muscles. At the same time it so acts on the liver that the blood circulating through that great organ becomes laden with blood-sugar.

We here obtain a glimpse of the neat and effective manner in which hormones are utilised in the economy of the living body. From that glimpse we seem to obtain a clue to that remarkable disorder of growth in the human body known as acromegaly. It is a pathological manifestation of an adaptational mechanism with which we are all familiar. Nothing is better known to us than that our bodies respond to the burden they are made to bear. Our muscles increase in size and strength the more we use them; increase in the size of our muscles would be useless unless our bones also were strengthened to a corresponding degree. A greater blood-supply is required to feed them, and hence the power of the heart has to be augmented; more oxygen is needed for their consumption, and hence the lung capacity has to be increased; more fuel is required—hence the whole digestive and assimilative systems have to undergo a hypertrophy, including the apparatus of mastication.

Such a power of coördinated response on the part of all of the organs of the body to meet the needs of athletic training, presupposes a coördinating mechanism. We have always regarded such a power of response as an inherent property of the living body, but in the light of our growing knowledge it is clear that we are here dealing with a hormonal mechanism, one in which the pituitary gland is primarily concerned.

#### *Production of Acromegaly.*

When we study the structural changes which take place in the first phase of acromegaly,<sup>8</sup> we find that not only are the bones enlarged and overgrown in a peculiar way, but so are the muscles, the heart, the lungs, the organs of digestion, particularly the jaws; hence the marked changes in the face, for the form of the face is determined by the development of the upper and lower jaws. The rational interpretation of acromegaly is that it is a pathological disorder of the mechanism of adaptational response; in the healthy body the pituitary is throwing into the circulation just a sufficiency of a growth-regulating substance to sensitise muscles, bones, and other structures to give a normal response to the burden thrown on the body. But in acromegaly the body is so flooded with this substance that its tissues become hypersensitive and respond by overgrowth to efforts and movements of the slightest degree. It is not too much to expect, when we see how the body and features become transformed at the onset of acromegaly, that a fuller knowledge of these growth mechanisms will give us a clue to the principles of race differentiation.

#### THE PATH OF FUTURE INQUIRY.

There must be many other mechanisms regulated by hormones with which we are as yet totally unacquainted. I will cite only one instance—that concerned in regulating the temperature of the body. We know that the thyroid and also the suprarenal glands are concerned in this mechanism; they have also to do with the deposition and absorption of pigment in the skin, which must be part of the heat-regulating mechanism. It is along such a path of inquiry that we expect to discover a clue to the question of race colour.

This is not the first occasion in which the doctrine of hormones has been applied to biological problems of the British Association. In his Presidential address to the Zoological Section at Sheffield in 1910 Professor G. C. Bourne applied the theory to the problems of evolution: its bearing was examined in more detail in an address to the same section by Professor Arthur Dendy during the meeting at Portsmouth in 1911. At the meeting of the Association at Newcastle in 1916 Professor MacBride devoted part of his address to the morphogenetic bearings of hormones. Very soon after Starling formulated the hormone theory, Dr. J. T. Cunningham applied it to explain the phenomena of heredity.<sup>7</sup> Nay, rightly conceived, Darwin's theory of Pan-genesis is very much of the same character as the modern theory of hormones.

## "HETEROSEROTHERAPY" IN PULMONARY TUBERCULOSIS.

By J. J. PERKINS, M.B., F.R.C.P.,

PHYSICIAN TO ST. THOMAS'S AND THE BROMPTON HOSPITALS;

R. A. YOUNG, M.D., F.R.C.P.,

AND

W. O. MEEK, M.B.,

MEDICAL SUPERINTENDENT, THE FRIMLEY SANATORIUM.

(From the Brompton Hospital Sanatorium, Frimley, Surrey.)

AN attack of acute pleurisy with serous effusion occurring in the course of chronic pulmonary tuberculosis, with subsequent spontaneous absorption of the effused fluid, is followed not infrequently by a prolonged period of improved health and a marked amelioration of pre-existing symptoms. This improvement has been ascribed to the mechanical action of the effusion in compressing and immobilising the subjacent lung, an action comparable to that of gas artificially introduced into the pleural cavity for this purpose or to that of the accumulated serous fluid in a case of hydro-pneumothorax. This explanation seems doubtful in view of the fact that the duration of an intercurrent attack of pleurisy with effusion is usually limited to a period of three weeks, sometimes less. It entirely fails to explain the improvement witnessed in those cases where the effusion has occurred on the side of the sounder or (in instances of unilateral disease) the apparently sound lung.

Of late years the treatment of tuberculous serous pleural effusion has become more conservative and paracentesis is reserved by many for those cases where the accumulated fluid is dangerous in virtue of its bulk or where natural absorption is unduly delayed. In fact, it is becoming recognised that the patient gains "something" from his effusion; it is difficult to be more explicit.

One of us (W. O. M.)<sup>1</sup> has pointed out elsewhere that the amount of specific antibody (as estimated by means of the "complement-fixation reaction") in the blood-serum of a consumptive individual may show marked fluctuations during an intercurrent attack of acute pleurisy with effusion. R. C. Paterson,<sup>2</sup> whose work throws fresh light on the subject of the tuberculous serous effusion, concludes that "clinical pleural effusions are caused by the infection of an allergic pleura." V. Gilbert<sup>3</sup> of Geneva, in 1896, published details of the treatment of sero-fibrinous pleurisy by "autoserotherapy." He advocated the withdrawal of a small amount of fluid from the pleural cavity and the inoculation of 2 c.cm. into the patient's own subcutaneous tissue. He stated that this procedure was followed by (a) a reaction evidenced by a transient rise of temperature of 1°-2°, (b) increased diuresis with a fall of temperature, and (c) rapid absorption of the effusion in from six to ten days. A. Jousset,<sup>4</sup> in 1912, while not admitting the value of "autoserotherapy," suggested the employment of "heteroserotherapy" in the treatment of chronic tuberculous pleurisy, stating that tuberculous pleural effusion fluid may be protective to guinea-pigs. He recommended that the fluid withdrawn from cases of acute serofibrinous pleurisy should be allowed to clot and the serum be pipetted off and sterilised by heating to 55° C. on three successive days. This sterile serum was to be employed in doses of from 20-50 g., by subcutaneous inoculation, in the treatment of other patients suffering from chronic tuberculous pleurisy.

*Details of Treatment.*

In 1917-18 we employed the method of "heterosero-therapy" in the treatment of a few cases of pulmonary tuberculosis. The following is a brief account of our experience:

*Source of the tuberculous effusion fluid employed.*—Fluid from five cases of pleurisy was used: (a) Two cases of "primary" tuberculous pleurisy with effusion, from the wards of St. Thomas's Hospital, diagnosed on clinical grounds and on cytological examination of the aspirated fluid. (b) Three cases of acute pleurisy with effusion complicating "open" pulmonary tuberculosis in patients at the Frimley Sanatorium.

*Collection and preparation of the fluid.*—The effused fluid was withdrawn from the "donors'" chests by the usual method, with aseptic precautions, into flasks containing a 2 per cent. solution of sodium citrate in normal saline, the final proportion of pleural fluid to citrated saline being roughly as 3 to 1. The fluid was examined cytologically, and in some instances a rough estimation of the number of lymphocytes to the cubic centimetre was made. Sterilisation was effected by adding to the fluid one-tenth its volume of a 5 per cent. solution of carbolic acid, the addition being made gradually with constant stirring. Even so, some coagulum forms, but it is small in amount and, if the fluid is shaken before use, the slight flocculent deposit is insufficient to block a moderately stout hypodermic needle. Finally, the fluid was stored in the cold in convenient hermetically sealed vessels. From the above it will be seen that all the constituents of an unbeat effusion were employed for inoculation.

*Dosage.*—The fluid was administered by inoculation into the subcutaneous tissues. For obvious reasons the initial dose was small (1-2 c.cm.). The amount was increased gradually up to 10, 15, or even 25 c.cm. At the commencement of a course of injections they were given twice or three times weekly; when the larger doses were reached, as a rule at weekly intervals. The injections never caused any disquieting symptoms. Occasionally a transient small rise was noted in the evening temperature on the day of administration. This occurred with some regularity in Case C alone of the eight cases treated. In another instance, where the temperature had fallen to normal during treatment, a dose was sometimes followed by an evening temperature of 99° F. In no instance was a sudden marked rise of temperature, comparable to that produced by an overdose of tuberculin, witnessed. Where improvement in the patient's condition coincided with the administration of the pleural fluid, it was most marked when a dose of about 10 c.cm. had been reached.

*Selection of cases for treatment.*—As will be seen from the subjoined clinical abstracts, all the cases treated, with the exception of D, had extensive active disease of the lungs, and in all, with the same exception, the outlook seemed very grave. The patients, C, G, and H appeared to us to be moribund at the time treatment was commenced. All, except Case C, were undergoing sanatorium treatment at the Frimley Sanatorium and had been there for some months previous to the administration of the pleural fluid. In every instance tubercle bacilli were present in the patient's sputum.

*Details of Cases Treated.*

(A) Male, 39, eight years' history. Admitted June 6th, 1917. Extensive active bilateral disease and extensive laryngeal ulceration. Evening temperature 100°-101° F. Very distressing laryngeal symptoms. Rest in bed for two months effected no improvement, and his condition steadily deteriorated. On August 13th injections of pleural fluid were commenced with a dose of 1 c.cm. gradually increased up to 15 c.cm. by the end of September and continued until Oct. 16th, when they were omitted. During this period the temperature fell gradually and remained about normal, the laryngeal symptoms disappeared in a remarkable manner, the patient gained some weight and was well enough to be up and about. His condition remained satisfactory until Nov. 22nd, when the temperature again rose to 100° F. Injections of 10 c.cm. of pleural fluid were recommenced and continued until the patient was discharged on May 8th, 1918. During the second course of injections the temperature fell rapidly and remained satisfactory, not reaching 100° F. again, and only twice exceeding 99° F. He returned to light work at his home and reported in August, 1919, that he had been constantly at work with continued improvement in his health.

(B) Male, 21, 12 months' history. Signs of active disease throughout the right lung, with infiltration of the upper lobe of the left lung. Admitted May 2nd, 1917. Evening temperature about 100° F. After 10 weeks' rest in bed the general condition showed no improvement and the temperature was higher. On July 19th a right-sided artificial pneumothorax was induced, and compression of the lung kept up until August 24th. The lung collapsed readily, and the pneumothorax was apparently complete. (No X ray examination.) This having no effect upon the pyrexia or other symptoms, injections of pleural fluid (1 c.cm.) were commenced on August 13th. The amount was increased gradually up to 25 c.cm. on Nov. 5th, on which date the injections were discontinued. The temperature began to fall when a dose of 7 c.cm. was reached, and after a few doses of 10 c.cm. rapidly assumed a more favourable type, being practically normal by Sept. 27th, and from this date until Nov. 20th rarely exceeded 99° F. and was never higher than 99·4° F. During this period the patient gained 12 lb. in weight, was able to get up for most of the day, and the symptoms and general condition were improved. On Nov. 20th, 21st, and 22nd the evening temperature was 99° or 99·2° F., and injections of 10 c.cm. of pleural fluid were recommenced and continued until Feb. 8th, 1918. During this time the temperature remained satisfactory, weight was maintained, and the patient was well enough to be up all day and to take exercise. He relapsed subsequent to discharge, and in June, 1919, was reported to be going downhill.

(C) Male, 16, two months' history. Seen Feb. 12th, 1918. Acute caseous tuberculosis of both lungs. Tuberculous laryngitis. Pyrexia (temperature up to 103° F.). After two months' rest in bed the temperature improved (ranging up to 100° or 101° F.), he had gained a few pounds in weight, and the general condition, while still grave, showed slight improvement. Between April 7th and June 12th he had 23 doses of pleural fluid from 2 to 10 c.cm. During this period the temperature fell further, the general condition improved, he gained 10 lb. in weight, and became well enough to go to a sanatorium. Subsequently the laryngeal disease increased, and he died about Christmas, 1918. In this case the administration of the earlier doses of pleural fluid was followed frequently by a slight elevation of temperature with a subsequent fall.

(D) Male, 48. Admitted Dec. 28th, 1916. Seven years' history. Chronic tuberculosis of right lung. Recent activity. Slight pyrexia and constant hæmoptysis of small amount. In March, 1917, acute bilateral tubercular epididymitis developed. One testicle was removed in April and the second in June. This was followed by a prolonged period of slight pyrexia, with occasional rises of temperature to 100° or 101° F., and persistent slight hæmoptysis. From Dec. 24th, 1917, to May 3rd, 1918, he had 35 injections of pleural fluid in doses of from 2 to 10 c.cm. (346 c.cm. in all). By February the temperature had fallen to 98·4° F. or below, and thereafter remained stable. The hæmoptysis ceased at the end of this month and did not recur. The pulmonary symptoms were reduced to a minimum, and in May he was well enough to resume active work and has remained well ever since.

(E) Male, 24. Admitted May 16th, 1917. A few weeks' history.—Acute bilateral disease. Continuous pyrexia and frequent hæmoptysis. By November the general condition had improved slightly, the evening temperature ranging up to 101° F. From Nov. 13th, 1917, to March 1st, 1918, he had 35 inoculations of pleural fluid (300 c.cm. in all). During the administration the temperature fell and remained much more stable, though he did not become actually afebrile. (Average evening temperature 99° F.) The improvement in general health was marked. In April, 1918, a prolonged period of fever set in and the temperature remains unstable at the time of writing, though the improvement in general condition has been maintained.

(F) Male, 23. Admitted Sept. 26th, 1917. Nine months' history. Extensive disease of the right lung and ulceration of the larynx. Slight pyrexia with irregular rises of temperature up to 102° F. From Nov. 21st, 1917, to Jan. 15th, 1918, had 18 injections of pleural fluid (1 c.cm. to 10 c.cm.). There was no apparent effect on temperature or general condition. He subsequently improved and reported in June, 1919, that he had returned to America and was in better health.

(G) Male, 47. Admitted Nov. 14th, 1917. Eighteen months' history. Extensive bilateral disease with advanced laryngeal and pharyngeal tuberculosis. Apparently moribund. From Jan. 18th, to Feb. 28th, 1918, had 14 doses of pleural fluid (3 c.cm. to 10 c.cm.). They had no effect, and the patient died in April.

(H) Female, 21. Admitted Nov. 30th, 1917. Eighteen months' history. Extensive bilateral disease. Pyrexia. In February, 1918, there was evidence of marked extension of disease, and the general condition deteriorated. From May 1st to July 5th 12 doses of pleural fluid were given (110 c.cm. in all) with no effect. The patient continued to go rapidly downhill, and died in the winter.

*Summary.*

In three (F, G, and H) of the above eight cases the administration of the pleural fluid was without any apparent effect upon the symptoms or course of the disease. In two (C and E), where improvement coincided with treatment, it must be admitted that these two patients had shown signs of improvement before it was commenced. Two (A and B) were going steadily downhill in spite of other measures of treatment; in both the use of pleural fluid was followed by rapid and marked improvement, in both the cessation of the injections was followed by a tendency to relapse, and in both renewed improvement followed their resumption. Both these patients received injections of the same pleural fluid (from a case of "primary" tuberculous pleurisy) used within a few weeks of its preparation.

In the remaining case (D), though the patient's general condition was good throughout, troublesome symptoms which had persisted for months disappeared within a few weeks of the administration of the pleural fluid.

While well aware of the difficulty of correlating cause and effect in a case of tuberculosis of the lungs, we are of opinion that the use of "heteroserotherapy" in this disease is worthy of further investigation, and that the results obtained in Cases A, B, and D may be ascribed fairly to the effect of the inoculated pleural fluid.

## THE EARLY TREATMENT OF MENTAL DISORDERS.

BY R. EAGER, M.D. ABERD.,

SENIOR ASSISTANT MEDICAL OFFICER AND DEPUTY MEDICAL SUPER-INTENDENT, DEVON MENTAL HOSPITAL, EXMINSTER; MAJOR, R.A.M.C. (T.); LATE O.I.C. MENTAL DIVISION, THE LORD DERBY WAR HOSPITAL, WARRINGTON.

AT the present time, when articles are constantly being published with regard to the extraordinary good results obtained in the treatment of the psychoneuroses in special neurological hospitals, I think it will not be out of place to record the results obtained amongst the psychoses.

*The Material Examined.*

I am taking my figures from the admissions to the Mental Division of the Lord Derby War Hospital for the first two years. There were during this period 4695 admissions, all of whom were soldiers in a state of acute mental disorder, and by far the majority came from the Expeditionary Forces overseas.

Amongst this vast number of cases of acute mental breakdown all types were met with. Speaking generally, there was nothing very noticeable in the way of symptoms presented to differentiate them from those seen in pre-war experience. I have already recorded the individual types of psychoses met with in a paper published in the *Journal of Mental Science* of July, 1918, and will therefore not enter into the discussion of individual cases in this article.

A survey of the numbers of admissions and discharges at the end of two years' work discloses the fact that the recovery rate stands at 56 per cent., and I think this is sufficiently encouraging to call attention to, seeing that the percentage of recoveries amongst male admissions to county and borough asylums in England for the 10 years 1902 to 1911 inclusive was only 32 per cent.<sup>1</sup> A statistical record of the admissions from the French Expeditionary Force will be found in Table III.

Of the 1000 cases in hospital at the end of two years' admissions only 200 had been resident six months or over, and during this period the deaths totalled only 40, or 0.8 per cent.

Over 330 cases who had developed a mild psychosis under exceptionally trying conditions were considered sufficiently recovered to justify their return to military duty under the proviso that they were kept on home service for 12 months.

This step was so far justified that a great number of these ultimately again went to the front, the wisdom of which, however, is a question for speculation.

*Review of Treatment Adopted: 1. Early Observation.*

I propose, therefore, to review the treatment adopted in dealing with this vast number of cases of acute mental disorder.

In the first place, I think an important point is that all were brought under observation at the earliest possible period of their trouble and placed under medical officers with special experience of such conditions. At the same time, this segregation was as far as possible relieved of any stigma. No patient was under any certificate, and no legal formalities had to be gone through before he was placed under the special treatment. As soon as possible, after his condition improved sufficiently, he was allowed parole and all the privileges of a case in the surgical or medical wards of the hospital. The Lord Derby War Hospital was, in fact, a general hospital with medical, surgical, and mental divisions, of which the latter comprised 1000 beds. Apart from the fact, therefore, that his mental condition prevented it, just as a case in the surgical or medical wards might be similarly prevented by his disability, a patient was as soon as possible allowed to mix freely with patients from other parts of the hospital. Any distinction was avoided.

The bringing of these cases under early observation was helped considerably by the facilities in detecting premonitory symptoms. If a soldier in the army, who has been previously up to the average standard, is noticed to be unable to stand properly to attention on parade, or does not form fours properly, or in any other way does not seem up to his usual standard, it is almost certain that this will be reported by his N.C.O. to a superior officer, who will ultimately send him to be examined by the medical officer. Even off duty, when in billets or barracks, he is more or less under observation, and by night more especially so. It is therefore likely that any strange action will be noticed and reported. In civil cases, on the other hand, this early detection of symptoms is much more difficult, and patients are much more likely to be able to conceal their symptoms. This point has been brought out by my colleague, Captain O. P. N. Pearn, R.A.M.C., in his article on the Psychosis in the Expeditionary Forces, recently published in the *Journal of Mental Science*.<sup>2</sup> I feel sure that the patient, as a civilian under present conditions, knows that by disclosing his feelings he will be brought before a medical man, who will probably call in the assistance of a magistrate, that he will deprive him of his freedom, and at the same time subject him to the stigma of certification and all its necessary legal accompaniments. Under such conditions symptoms are concealed as long as possible, and in the early stages, as a rule, the patient does not find much difficulty in "pulling himself together" sufficiently to pass muster in his office as a clerk, or whatever occupation he may perform. In a city he probably does not return home to his midday meal or tea, but has these at a restaurant, where it is no one's business in particular if he does anything strange. He probably returns home late at night, and spends little time in the company of his friends or relations. This sort of thing often goes on for months or even years undetected, until he ultimately commits some act against the conventions of society by which he gets into the hands of the police. In the soldier, on the other hand, as treated during the war, no stigma was attached to the fact that he became insane. He was, as far as practicable, treated as any other casualty, and if he reported his symptoms voluntarily, was taken to a hospital in the same way as if he were suffering from any other illness.

*2. Adequate Medical Staff.*

Another point is the importance of having an adequate medical staff in dealing with cases at this stage. A glance at Table I., which shows the monthly admission and discharge rate during the two years under consideration, will indicate the necessity for a large medical staff to deal with such numbers alone. At the opening of this special psychiatric section it was strongly urged that the relative strength of medical officers should be no less than 1 to every 100 patients.

Apart from the question of dealing with large numbers it must be remembered that if patients are to have adequate treatment in the early stages of mental disorder, the relative

TABLE I

●—● = Actual admissions during the month  
 ○—○ = " discharges " " "  
 ■—■ = Average admissions " " "  
 □—□ = " discharges " " "

number of doctors must be increased much above that which is customary in present-day asylum practice. From the experience I have had I would advocate that there should be no less than 1 medical officer for every 50 patients, if all that is possible is to be done for such cases.

In making this statement I am, of course, intending it to apply to a hospital dealing solely with early cases of mental disorder, and am not supposing that the chronic cases will be included or retained, if admitted.

To undertake work which, if carried out properly, meant spending many hours a week with individual cases, was quite out of the question with a staff of only 1 in 100, in addition to the fact that, at times, when medical officers were urgently needed elsewhere, even this proportion could not be maintained. As much as possible, however, was done.

A great deal has been written lately about the treatment of the psychoneuroses by suggestion and persuasion, using these terms to cover all the different modifications, such as hypnotism and treatment with the aid of electricity, which comes under their meaning. Also the amount of individual attention and time that has to be given to each case. The same applies to the treatment of the psychoses, and in many cases is the sole means of saving them from running a chronic course. It is true that some cases appear to recover with "quiet and rest," and treatment by what Dr. T. E. K. Stansfield<sup>3</sup> has called "rational" lines, but there are a great number in which every means of suggestion and persuasion must be exercised with tact and perseverance and untiring patience upon the part of the medical officer. In these cases—more so than in the psychoneuroses—comes the importance of psycho-analysis, using this term in its widest sense and not necessarily meaning Freudian psycho-analysis, as is so commonly concluded by those opposed to this method. I am certain that individual attention and analysis, as a rule, fully justified the expenditure of time necessary for such methods, the principles of which have been so aptly and ably described by Bernard Hart,<sup>4</sup> who teaches that it is becoming more and more certain that the mental factor forms the most important link in the chain of causation in

the psychoneuroses and has drawn attention to the underlying conflict between the instinct of self-preservation and the sense of duty and patriotism in the case of the soldier. (¶)

As has been pointed out by Eder,<sup>5</sup> "psycho-analysis is the only method that enables the patient to deal with the underlying state, and not merely with the symptom. In psycho-analysis the patient learns for himself the real significance of his disease, a privilege only acquired by a bitter self-realisation. The 'rest cure' affords the ideal conditions for retirement from life's duties, and strengthens the patient's motives for remaining ill, but by psycho-analysis the unconscious mind is explored and the energy hitherto wasted in internal conflict is made available for the purpose of life."

#### Usual Procedure on Admission.

On admission of patients to the Mental Section of the Lord Derby War Hospital, they were taken straight to the admission ward, where clerks obtained particulars for the admission and discharge book. Each medical officer was provided with a private room in his wards, where, at his convenience, he could interview each patient separately, with the full assurance that his statements would be treated as confidential. The case sheets of each patient in the ward were kept in this room under lock and key as confidential documents, and not hung up with the chart over the patient's bed, as in ordinary hospital wards. Everything, in fact, was done to inspire confidence between the patient and the doctor, and it is only in this way that one can expect such cases to really enter freely into examination, to coöperate with the doctor and interpret their feelings, as the result of which the benefits of psychotherapy become very strikingly obvious. It is not to be expected that such can be carried out either in an open ward with numbers of other patients listening to everything said, or in a room in which anyone else is present except the physician and the patient. Beds in the open air were provided for those to whom it was thought rest in bed would be beneficial, and as soon as possible patients were allowed to have freedom from lock and key.

No selection as to the type of case admitted was possible. Amongst such a vast number of admissions it is not surprising therefore that the number of cases of general paralysis alone came to 197.

The above facts must be borne in mind when considering the recovery-rate, in addition to which I should add that the number of cases of congenital mental defect reached no small figure. Even in these cases, however, many showed acute symptoms superimposed on this congenital defect. A number of cases received had been previously in special neurological hospitals, and were transferred to the mental section as they had not improved. These admissions also tended to reduce the percentage of recoveries.

Cases found to have been previously under asylum care in peace-time, all epileptics, and cases of G.P.I. were certified and transferred to asylum care as soon as the diagnosis had been confirmed. Similarly all cases who had been resident nine months without showing any appreciable signs of improvement, were so transferred, and in this way the hospital was kept as free as possible from chronic cases and an atmosphere of cure was prevalent. The total transferred to asylums was 452 (or 9 per cent.).

A number of cases were transferred to other hospitals in Scotland, Wales, or Ireland so as to be nearer their relatives for visiting purposes, and a larger number of Colonials were repatriated to the Colonies for final disposal. A large proportion of these cases were well on the road to convalescence before they left, but as their final condition was not determined, they have not been included in the percentage of recoveries. Whilst under treatment, any man having a special trade was given facilities for working at this in hospital workshops during his period of convalescence prior to his discharge, and in this way prepared himself for the work he would be taking up when leaving the hospital. This helped in a large measure to establish the man's confidence. Other cases, numbering about 100 daily, were encouraged to work on the farm and in the grounds. Idleness was discouraged, but absolute rest in bed in certain cases of exhaustion psychoses, on the other hand, was insisted on for purposes of treatment.

### 3. An Abundant Diet.

Next I should like to draw attention to the question of diet. A liberal nourishing diet is of the greatest importance in treating all cases of acute mental disorder. The diet as issued to the patients in the Mental Division of Lord Derby War Hospital will be seen laid out for the week in Table II. The allowances are much more liberal than those

TABLE II.—Specimen Dietary for Patients on Ordinary Diet.

—	Breakfast.	Dinner.	Tea.	Supper.
Sunday.	Tea, bread and margarine, with boiled bacon (4 oz. uncooked).	Roast beef (8 oz. uncooked), potatoes (12 oz.) and green peas (2 oz.), and milk pudding.	Tea, bread, margarine, and currant cake.	Coffee or cocoa and cheese (½ oz.).
Monday.	Tea, bread and margarine, with one egg.	Meat pies (beef, 8 oz. uncooked), potatoes (12 oz.), and haricot beans (1 oz.), with milk pudding.	Tea, bread, margarine, and jam (1½ oz.).	"
Tuesday.	Porridge, milk, tea, bread, and margarine.	Hot boiled bacon (6 oz. uncooked), potatoes (12 oz.), sufficient cabbage, and milk pudding.	"	"
Wednesday.	Tea, bread, margarine, and sausage (4½ oz.).	Steamed fish (12 oz. uncooked), potatoes and boiled suet pudding (ginger, collage, or jam roll).	"	"
Thursday.	Tea, bread and margarine, with one egg.	Roast beef (8 oz. uncooked), potatoes, and sufficient fresh vegetables and milk pudding.	Tea, bread, margarine, with currant bun or scone.	"
Friday.	Tea, bread and margarine, with sausage (4½ oz.).	Hot pot (beef, 8 oz. uncooked), peas pudding (split peas, 2 oz.), with milk pudding.	Tea, bread, margarine, and jam (1½ oz.).	"
Saturday.	Tea, bread and margarine, with one egg.	Hot boiled bacon (6 oz. uncooked), potatoes, and sufficient cabbage, with milk pudding.	"	"

Notes.—Daily allowances: Bread, 12 oz.; margarine, 1 oz.; sugar, 1½ oz.; milk, 9 oz., with 15 oz. for milk puddings and 10 oz. with porridge. Tea, ½ oz. per day; coffee, ½ oz., or cocoa, ½ oz.

allowed by the average civil asylum scale. The cost of this dietary alone in a civil institution would probably exceed 13s. per head per week on pre-war prices, whereas the average cost of maintenance up to the end of 1918, in civil asylums in this country, was only 14s. 5½d., and this is stated to be a rise of 1s. 9d. on the cost of the previous year.<sup>6</sup> It must also not be forgotten that this cost of maintenance includes provision for the salaries of the staff for these institutions. In addition to the above standard dietary, in some cases, patients were put on milk and eggs as extras, but the necessity for this did not often arise with such a substantial diet as a foundation.

### 4. Facilities for Specialist Treatment.

Another special feature which I should mention, and from which, I am certain, many patients derived much benefit, was the facility that existed for any patient being seen in consultation by a specialist for practically any bodily disorder of which he might complain. A spirit of confidence therefore existed amongst the patients that every complaint would at once receive thorough investigation. Numbers of cases on this account were sent to special departments of the hospital for examination or treatment. I would especially mention the eye department, the ear, nose, throat, X ray, electro-therapeutics, and massage. If any patient made a complaint with regard to physical symptoms, it was the invariable rule to call the medical officer in charge of the medical or surgical divisions of the hospital in consultation, and similarly with other special branches in order that the patient should receive the best possible treatment or advice. The London Hospital scheme of appointing a whole-time salaried physician of the highest standing instead of the honorary appointment, where visits are made periodically, has already been introduced in some hospitals, as it was felt that the best results could only be obtained under conditions where the doctor was on the spot. It was certainly most helpful in dealing with large numbers of acute psychoses.

A specially trained masseur was employed in the mental section to attend cases having surgical disabilities complicated by a psychosis. There were numerous cases of this kind, as would be expected, seeing that most of the admissions came direct from the firing line or front-line area. Cases in a generally debilitated exhausted state were also treated with general massage in some instances. There were 18 of these. About an hour was devoted to each case at a sitting, and treatment was given three days a week, extending in some instances to three months in duration. The improvement in general condition was very striking, and in all cases the mental condition improved with accompanying psychotherapy.

### Surgical Cases.

Amongst the surgical cases special investigations were made into a hundred cases of head injury with accompanying mental symptoms, which I have made the subject of another article.

No corroborative evidence was found to substantiate Holländer's<sup>7</sup> statements that loss of intelligence occurs in frontal injuries, melancholia in parietal injuries, mania in temporal injuries, or that in the case of occipital injuries the gregarious instinct is especially effected. On the contrary, it was clearly shown from 27 cases of frontal injury that there was no uniformity in the mental symptoms that may follow injuries to this part of the head, and this statement is applicable to the skull generally.

A large number of cases of epilepsy occurred in gross lesions of the parietal region of the skull, and my results in this respect agree with those of Roeper.<sup>8</sup> The preponderance of cases of amnesia were found in frontal injuries, but, with these exceptions, no symptoms could be definitely associated with injuries to any special region of the skull.

### Cases of Venereal Disease.

Amongst other cases, about which some special consideration might be made, are the cases of venereal disease. There were 305 cases suspected of being so infected, and tested by the Wassermann method. Of this number 249 gave a positive blood reaction and 172 a positive reaction in the cerebro-spinal fluid. The globulin test was positive in 123, and in 109 there was an increased cell count.

Prior to the discovery of this method of testing a patient's bodily fluids it was, in many cases, mere guess-work to say whether this or that person, at some time or other, had or had not suffered from syphilis. Any expressions of opinion

as to the rôle of syphilis in the causation of mental disease must have been merely speculative. At the present time, however, it must be accepted that, provided the Wassermann test is performed by a specially trained pathologist, who has had special experience in its technique, the percentage of positive Wassermann reactions in active syphilis is so high that the test may for all practical purposes be looked upon as decisive.

Major C. F. White and Captain A. T. McWhirter and Captain H. Barber,<sup>9</sup> as a result of their experience of 5800 Wassermann tests, say that they are satisfied that syphilitic serum gives a positive result and non-syphilitic negative in such an overwhelming majority of cases that any apparent exceptions must be very closely studied before they are accepted. A full course of 606 injections was given in 11 cases in which the blood only was positive. Nine of these cases were ultimately discharged recovered from their mental symptoms. The complete conversion of the positive Wassermann reaction in the blood was, however, only obtained in four of these cases. It must be remembered, however, that the history of infection was at a very remote period, and that, apart from the mental symptoms, there were no active signs of syphilis.

The method of treatment adopted was to give salvarsan or its equivalent combined with mercury as follows:—

	Salvarsan	Mercury.
1st day ... ..	0.3 g. ....	1 gr.
4th " ... ..	0.3 " ....	0 "
8th " ... ..	0.3 " ....	1 "
15th " ... ..	0 " ....	1 "
22nd " ... ..	0.4 " ....	1 "
29th " ... ..	0.5 " ....	1 "
36th " ... ..	0 " ....	1 "
43rd " ... ..	0.5 " ....	1 "
50th " ... ..	0.5 " ....	1 "

The 606 injections were given intravenously by the gravity method, and the mercury injections were given intramuscularly into the buttocks. On the 52nd day the blood was again tested, and, if negative, treatment was suspended. In cases where the reaction was still positive, however, a course of pot. iod. was given till the 68th day and then the following injections:—

	Salvarsan.	Mercury.
69th day ... ..	0.3 g. ....	1 gr.
76th " ... ..	0.4 " ....	1 "
83rd " ... ..	0.5 " ....	1 "

If the blood was still positive after this, chronic mercurial treatment was advised. The derivatives of salvarsan used were kharsivan and arsenobillon, and the solutions were freshly prepared immediately before injection. In no case was there any dermatitis or other untoward symptoms.

The treatment of syphilis of the nervous system by prolonged intravenous injection of neosalvarsan has been shown by Henry Head<sup>10</sup> to have given good results in cases where the lesion is situated in parts, such as the meninges and vessels (meningo-vascular type), easily reached by a drug circulating in the blood. He states that not only is the disease affected favourably, but the Wassermann reaction, if positive in the c.s.f., may become negative within a few months after treatment, and the pleocytosis greatly reduced. In most cases this change was effected by three doses of 0.9 g. of neosalvarsan, but in a few instances even relatively smaller doses of salvarsan were used. On the other hand, in cases which do not improve with this treatment, he considers the affection is deeper-seated and out of reach of the arsenical compounds employed by that method. The conclusions arrived at by Head were that it is impossible by bedside examination to determine whether the patient is suffering from dementia paralytica or syphilitic encephalitis. Cases of syphilis meningo-vascularis cerebri may be distinguishable from dementia paralytica solely by the fact that the cerebro-spinal fluid from the first gives a negative reaction. But if, as so commonly happens, intraspinal complication is present the cerebro-spinal fluid in both may be equally positive.

#### General Paralysis.

With regard to the cases of general paralysis, there were in all 197 cases admitted under my care. Ten of these died before their transfer to asylum care could be carried out. Transfer to an asylum was the method of disposal of all

these cases as soon as the diagnosis had been confirmed by the laboratory findings. In 180 cases in which records of the reactions were made 168, or 94 per cent., gave a positive blood Wassermann reaction and 12 a negative. Amongst the latter, however, the negative blood reaction was associated in four cases with a positive reaction in the c.s.f., a positive globulin reaction and an increased cell count, leading to the supposition that the bloods had been converted by treatment, and in only two cases were all the results negative. The c.s.f. reaction was positive in 93 per cent., the globulin reaction in 94 per cent., and there was a pleocytosis in 87 per cent. The cell count in some cases reached as high as 400 per c.mm., but anything over 10 per c.mm. was looked upon as abnormal.

Captain Barker Charnock, R.A.M.C., pathologist to the hospital, has very kindly given me the following brief observations: "In general paralysis of the insane it is my experience that, as a routine, the blood serum and the cerebro-spinal fluid should be examined, together with the globulin content and the cell estimation of the latter. As an aid to the differential diagnosis of general paralysis, cerebral syphilis, and tabes, Lange's colloidal gold reaction is of great use; the only difficulty being the preparation of the water triply distilled from glass. A good glass still is required in the up-to-date laboratory. In spite of what is said to the contrary, I have found that the routine globulin reaction has been useful in early cases. It has been my experience that the globulin reaction may appear before the positive Wassermann reaction in the cerebro-spinal fluid. As a reliable test the Pandey method gives good results and is free from the obnoxious odour associated with the Noguchi reactions. The Alzheimer method has been of great use in demonstrating the plasma cells diagnostic of G.P.I. The quantitative method of performing the Wassermann test has been useful in judging the effects of treatment. This method has been controlled by the modified complement-fixation tests with and without the destruction of complement. Observations based upon the modified tests pointed out that the sera possessing the most potent complement usually reacted best to arsenical treatment."

These reactions are of the greatest importance in dealing with incipient cases of general paralysis of the insane, the correct diagnosis of which in this stage cannot be given unhesitatingly without their aid. In quite a number of cases the reactions to these tests changed from a negative to a positive finding whilst the patients were under observation, showing the early stage in which the condition existed. On the other hand, in cases in which the medical history sheet (A.F. 187) covered that period, the date of primary infection could be shown to be as long as 15 years before the onset of the symptoms.

A few of the early cases of general paralysis of the insane were given intrathecal injections of mercurialised serum, but in no case was a positive converted into a negative fluid reaction by this treatment, and hence no success can be claimed for it as far as my experience goes. All types of general paralysis of the insane were met with, and the impression gained was that the symptoms developed more rapidly than in the cases seen in pre-war days. A few died in a state of acute mania, with little to justify the diagnosis had not the reactions of the blood and fluid been tested, and I feel sure that many cases in the past who have died from so-called "acute delirious mania" belong to this category.

#### Lumbar Puncture.

The importance of performing a lumbar puncture and testing the spinal fluid reactions, especially in cases which in any way cause one to suspect incipient symptoms of general paralysis, cannot be over-emphasised. Up to the present cases are rarely diagnosed before the brain has undergone extensive and irreparable damage. Sir Charles Ballance and Dr. H. Campbell<sup>11</sup> have recently published an instructive article on this subject advocating treatment by introduction of salvarsanised serum into the lateral ventricles in the pre-clinical stage of the disease. They point out also that the demobilisation of the British Army and the probable increase of syphilis in this country make it highly desirable that any means which may have a remedial influence on syphilitic infections of the nervous system should receive careful study.

This all tends to emphasise the importance of any institution dealing with early cases of mental disorder being in close association with an up-to-date laboratory and

pathologist especially experienced in the technique necessary to perform this work. It also shows the importance of any institution for the early treatment of mental diseases being provided with adequate means for treating syphilitic affections by modern methods, and the need for closer coöperation between clinician and pathologist than has been customary in the past.

\* Including feeble-mindedness, idiocy, and imbecility.

† Associated with acute infective disease.

#### Correction of Refractive Errors.

A large number of cases complaining of persistent headache were sent to the ophthalmic department of the hospital for special examination, and on the refractive errors being corrected rapid improvement resulted in the accompanying mental symptoms.

Captain R. Richards, R.A.M.C., ophthalmic surgeon to the hospital, has very kindly given me the following particulars with regard to 129 cases examined. Of these cases, he states that "myopia accounted for 7; hypermetropia, 15; simple astigmatism, 11, myopic astigmatism, 14; hypermetropic astigmatism, 15; mixed astigmatism, 26; anisometropia, 41. In addition to the above 9 cases of presbyopia were corrected. The 41 cases specified under anisometropia were of a more or less pronounced character, but there were others which showed a much lesser degree of unequal refraction. Examination of the fundi revealed in many of the eyes conditions associated with pathological and traumatic factors, such as choroiditis, retino-choroiditis, choroidal atrophy, opaque nerve fibres, macular changes due to high myopia, ruptured choroid, and myopic crescents. There were also cases of nystagmus, corneal nebulae, corneal scars following perforating wounds, occlusion of pupil, &c. The cases proved quite an interesting series, and it is satisfactory to find that the improvement in the visual acuity of

those corrected added to their well-being and corresponding improvement in their mental condition. Ophthalmoscopic examination under the best conditions is not an easy matter, and one would be quite justified in coming to the conclusion that it would be much more difficult in patients mentally afflicted. This conclusion was, however, completely falsified; for, with only a very few exceptions, the very best of coöperation and assistance was obtained."

In the cases with refractive error I have little doubt that an error of refraction which had previously caused no trouble had given rise to severe headache, and superimposed mental symptoms in a man whose nervous system was exhausted as the result of active service.

#### Conclusions.

I should like to lay stress again on the benefit derived by the system of parole which was granted to convalescing cases. Although in the period of the two years on the average 300 cases daily were getting parole, only one case of concealed delusions managed to escape detection by the system adopted. I am quite certain that could such facilities be granted to convalescing patients in civil asylums and mental hospitals throughout the country a much healthier atmosphere would be created in these institutions. The granting of permission to these patients to go out for walks, not under supervision, for a couple of hours in the afternoon, would, I am certain, promote mental "well-being" and hasten convalescence. It would be looked upon as a privilege and would be seldom abused if sufficient care was exercised as to whom it was extended.

The experience I have gained by dealing with such a vast material of early mental cases has convinced me more than ever of the importance of early treatment. The fear of being certified and sent to an asylum existed as a prominent feature in many cases, and I cannot help feeling that a step in the right direction will be made if the lunacy laws are so amended as to allow of the treatment of early cases occurring amongst civilians on similar lines prior to certification. If this were possible, and such institutions were under the control of specially experienced medical men, I feel sure that a large number of cases of early mental disease would be provided with a much needed opportunity of obtaining advice and treatment at a time when there were some prospects of it being of some value. It was remarkable to see how cases cleared up with individual attention.

As things exist at present, however, a patient suffering from early mental trouble is denied treatment by a doctor who has specialised in that branch of medicine, for it rests with the private practitioner, with no special knowledge of the subject, to certify the patient. This, in the early stages, he naturally never does, owing to the stigma attached to such a procedure. The result is that such cases drift on from bad to worse for months or even years, and are prevented from being able to obtain the advice of those interested in their condition until the certificate stage is reached. In the case of the majority the damage has been done by this time. There was a similar state of affairs with consumptive disease in the old days, before the local authorities were given the power to appoint specially trained men to treat this condition in its early stages. I strongly maintain that the need is just as great now for the "mental clinic," especially as we are face to face with a tremendous reduction of the male population of the country through the ravages of war and also an emotional epidemic, which is quite common after a period of stress and strain such as the world has recently been through. Are all these cases, which might be directly or indirectly attributed to the war, to be deprived of treatment until they are so advanced as to be recognised as certifiable by the general practitioner?

No progress can be made in psychiatry in this country till Receiving Hospitals for psychoses in the early stages are introduced as a preliminary step to certification. It will be in these hospitals that the curable cases should be treated. The chronic cases should be sent to asylums, which have already become vast store-houses of chronic mental conditions. An atmosphere of cure, which is all-important in the early stages of treatment, is not possible in such an institution where the powerful force of imitation and suggestion by contact with chronic cases can only have harmful influence. To detach such a department from the soil in which it has grown for generations, and to effect a considerable change

in procedure which has hitherto been in vogue for so many years in order to bring this about, is going to be no easy matter. But if it is agreed that the task is worth undertaking, these difficulties must be overcome, and now, when the Ministry of Health Act is in its infancy, the time seems favourable for considering these changes seriously. For acute cases every modern method of psycho-therapeutic treatment should be available in order to hasten the return of the patient's mental condition to the normal. We want the best surroundings we can get with free access to consultative advice in all the other special branches of medicine, for it is only after a searching clinical, as well as psychological, examination that the particular lines of treatment for individual cases can be determined. For the chronic cases, on the other hand, nothing more can be done than to place them in as comfortable conditions as circumstances will permit. For the latter, there already exists a plentiful supply of asylums, which in this country rank amongst the best in the world for care and comfort, but for the former there is at present almost nothing at all.

## "TWILIGHT SLEEP" IN GENERAL PRACTICE.

By G. HAMILTON WINCH, M.B., CH.B. EDIN.

HAVING administered scopolamine-morphine anæsthesia to a series of 435 cases of parturition in private practice, I now record my results and experience of this treatment from a general practitioner's point of view. These cases were attended by me during a period of five years and nine months. During the first two years I was in a country practice in the Midlands, and during the remainder of the time I was in a London practice.

The method employed of producing anæsthesia was that developed by Gauss of Freiburg, which has become the standard, and to which he applied the term of "Dämmer-schlaf" (twilight sleep). The object of this method is to obtain not only a condition of analgesia, but also one of amnesia, or loss of memory for recent events. The importance of amnesia is, that it saves the mothers from physical and mental suffering and from fear of a succeeding labour. This state of amnesia does not cause loss of memory for previous events, but only an inability to remember what is happening while the patient is under the influence of this anæsthesia.

### *Technique.*

It is, of course, necessary to know the general condition of the patient, her pelvic measurements, and the position and presentation of the child. The only absolute contra-indication to this form of anæsthesia is primary uterine inertia. Contracted pelvis, dry labours, rigid cervix, eclampsia, and heart disease are not contra-indications. On the contrary, in some of my complicated cases, where operative treatment demanded chloroform, I very definitely found that much less was needed than in cases where "twilight sleep" was not used. Junker's apparatus has always been used by me in midwifery cases, and careful notes of the amount of chloroform used were taken. The amount used in "twilight" cases was, on an average, half the amount used in non-twilight cases.

As soon as labour begins the patient is put in the room chosen for her labour. When labour pains have caused dilatation of the cervix to the extent of admitting two fingers, and recur every five minutes in primiparæ, and not less than every seven in multiparæ, the treatment is commenced. First, the room is darkened, and the patient's ears are plugged with cotton-wool in order to help in the exclusion of any disturbing sounds. The first hypodermic

injection is then administered, consisting of morph. hydrochlor. gr.  $\frac{1}{4}$  and scopolamine hydrobromide gr.  $\frac{1}{150}$ . Here one may mention that it is important to use freshly prepared solutions of these drugs, which should be absolutely pure. I used tablets made by the following firms: Messrs. Evans, Sons, Lescher, and Webb, Messrs. Burroughs and Wellcome, and Messrs. Parke, Davis and Co., and always found them reliable. After this injection has been given, as a rule, in 20 minutes time the patient becomes drowsy and sleeps between the pains. During the pains she may still complain, but less so than before. At this stage it is advisable to carefully watch the patient's condition and frequently auscultate the fetal heart sounds. All being well, the second injection is given about one hour after the first; this and all succeeding ones consist of scopolamine hydrobromide gr.  $\frac{1}{450}$  only. In this series of cases I found that these subsequent injections were required every one or two hours, the interval becoming longer as the number of injections increased.

### *The Memory Test.*

The method of determining the depth of the anæsthesia and the need of a further injection was the application of the memory test. This was carried out as follows: One wishes to find out the stage at which the patient's memory for present events is absent, but on the verge of returning. The patient's temperature was taken in the axilla, and a few minutes later a pretence of taking it in the same way was made. If on inquiry immediately after the pretended act she did not remember the previous real act, she was deemed to be sufficiently "under." The least sign of returning memory indicates another injection. The number of these subsequent injections is of no importance. I have given 14 in one case without any harmful effect.

### *Important Points Noted During the Anæsthesia.*

In the great majority of cases the patient's face was decidedly flushed, and dryness of the throat was common. The latter condition was treated by administering frequent sips of water. In practically all the cases the patients never expressed any desire to pass urine. This was due, I think, to the fact that the amount of analgesia present nullified any pain caused by bladder distension. It is necessary, therefore, to note the condition of the patient's bladder and use a catheter when required.

The first stage of labour in these cases was nearly always definitely shortened as compared with non-twilight cases, especially in primiparæ. My experience is that this form of anæsthesia promotes dilatation of the cervix. On the other hand, the second stage of labour was nearly always prolonged; most of the delay occurring after the head had reached the perineum. This delay was not found to be in any way harmful to mother or child, even if of five or six hours' duration. In fact, owing to the gradual dilatation of the vaginal outlet, lacerations of the perineum were distinctly fewer than in non-twilight cases. In many of the cases I terminated the labour either by the use of the forceps or by the intra-muscular injection of pituitary extract. The former operation was in most of my cases carried out without the use of chloroform, and was done slowly and carefully. With regard to those cases, terminated by injection of pituitary extract,—I always used pituitrin (P., D. and Co.),  $\frac{1}{2}$  c.cm. in an ampoule—injecting a  $\frac{1}{2}$  c.cm. at first, and repeating it if necessary. It was distinctly observed that pituitary extract had not the same powerful effect in causing uterine contractions in these cases that it has in non-twilight cases. No bad effects on the fetal heart sounds were noted—that is to say, in none of my cases did the fetal heart-rate become unduly rapid (above 170) or unduly slow (below 100). Some of the patients exhibited a certain amount of restlessness and slight delirium, but not of sufficient account to interrupt the administration.

### *Birth of the Child.*

As soon as the child was born and the cord had been tied and separated it was removed to another room in order that its crying should not disturb the mother. This was always done when the child was born not cyanosed nor apnoic, but breathed and cried out spontaneously; in this series of cases such were in the majority. A comparatively small number—11.9 per cent.—were born cyanosed, and some were treated by artificial respiration; they all recovered. I found in a few of the cases where the baby was born

cyanosed that if simply left alone it returned to a normal condition after a considerable time.

#### Third Stage of Labour.

The mother was always carefully watched for atonic post-partum hæmorrhage, but this condition only occurred in 3.03 per cent. Two were cases of partially adherent placenta, where manual extraction was necessary. One other case occurred in a transverse presentation, where the version necessitated a good deal of manipulation and also the administration of chloroform in addition to the "twilight sleep." In all three the bleeding was controlled and good recoveries ensued. These cases were all multiparæ, the average number of injections per case being three. Perineal tears were remarkably few, the percentage being: primiparæ, 12.61 per cent.; multiparæ, 4.03 per cent. When they did occur they were immediately sutured without the use of chloroform.

#### Puerperium.

In the majority of the cases of this series the mother slept well for from two to six hours immediately after the completion of labour. The absence of shock was a most noteworthy feature in these cases. I was particularly struck by the excellent general condition of the mothers 24 hours after delivery. Lactation and involution proceeded quite as normally as in non-twilight cases, and apparently were in no way affected by the drugs administered; no other bad effects of this form of anaesthesia on the mothers were observed.

#### Conclusions.

"Twilight sleep" is of great value in obstetric practice, provided that it is administered in strict accordance with the technique laid down by Gauss of Freiburg. It certainly saves the mother from much pain, fright, and from shock. There are no ill-effects to mother or child.

Having been able to follow up the after-history of my cases, both as regards mother and child for a period of four years, I can confidently assert that I have not seen any harmful effects on either the mother's or the child's health which could be attributed to the use of this "twilight sleep" method.

The main disadvantage of the method in private practice is that it requires far more time and careful personal attention than are needed in ordinary labour cases. It has always seemed to me, however, that the extra time and trouble are well spent, for surely any woman has the right to be protected from unnecessary pain and suffering during parturition. I am not in agreement with those who state that labour is a normal physiological process and should be left to Nature as much as possible. Modern civilisation has so changed the average woman of to-day that parturition is no longer the easy process it was reputed to be in less civilised times. I am quite convinced that "twilight sleep" can be just as efficiently carried out in the patient's own home as in a hospital or nursing home. The following case, as being unique in many respects, is quoted in full:—

Mrs. —, primipara, age 43 years. Healthy. Pelvic measurements normal. Labour commenced at 9 A.M. on Sept. 29th, 1917. Examination revealed normal position of child; vertex presentation; L.O.A. At 11 A.M., when pains recurred every five minutes and cervix admitted two fingers, the first injection was given. Twenty minutes later patient was drowsy and sleeping between pains, but moaning during pains. The following injections were given after memory test: second, at 11.45; third, at 1.5 P.M. (patient at this stage—face flushed, very little thirst, and during uterine contractions quiet); fourth, at 2.35 (patient's condition as above); fifth, at 4 P.M.; sixth, at 5.45; seventh, at 7.15; eighth, at 8 P.M.; ninth and last, at 10 P.M. Baby girl born at 10.30 P.M. Placenta 11 P.M. No forceps or pituitrin used. No post-partum hæmorrhage. No perineal laceration. Baby breathed and cried out spontaneously. Mother slept for six hours after completion of labour.

The chief interest of this case was the fact that during the latter part of the labour—i.e., from about 7.30 P.M. onwards—one of the worst enemy air-raids over this district of London was taking place, and some bombs were dropped within a short distance of this particular house. Careful inquiry from the patient afterwards revealed the fact that she did not know until some hours after her labour was over that an air-raid had taken place. Mother and child made splendid progress, and at the present time are both in

excellent health. The baby is now 1 year and 7 months old. [A photograph of the child was submitted bearing out this statement.]

## HYPERKERATOSIS OF THE HAIR FOLLICLES IN SCURVY.

By HAROLD WILTSHIRE, O.B.E., D.S.O., M.D., F.R.C.P.,  
PHYSICIAN TO KING'S COLLEGE HOSPITAL; LATE ASSISTANT  
CONSULTING PHYSICIAN, B.S.F.

In dealing with some 3000 cases of scurvy which occurred amongst Serbian troops it was noticed that a condition of hyperkeratosis of the hair follicles was commonly present, in addition to those skin changes which are generally described as proper to this disease. The latter are: (a) an increase in dryness and roughness of the whole skin; and (b) a petechial rash due to small hæmorrhages occurring mainly in connexion with the hair follicles.

#### Occurrence of the Skin Changes.

**Frequency.**—The frequency of these follicular changes in scurvy is shown by the following analysis of 78 consecutive cases, which were under special observation with reference to another point<sup>1</sup>:—

Changes of petechial type only .. .. .	9 per cent.
" keratotic .. .. .	32 "
Both petechial and keratotic types present in ..	55 "
same individual .. .. .	1 "
No abnormal follicles .. .. .	4 "

From this it is seen that the proportion showing follicular hyperkeratosis amounted to no less than 87 per cent.

**Distribution.**—The follicles which showed this change were usually limited to the lower extremities, the favorite sites being the front and inner aspects of the thighs and the upper parts of the legs. When they were numerous in these regions—and in some instances nearly every follicle was affected—those of the pubic hairs were often affected as well (20 per cent. of the cases mentioned above), and sometimes those of the backs of the wrists and forearms (2.5 per cent.).

**The individual follicle.**—Each affected follicle presented a hard conical swelling about the size of a pin's head, owing to a collection of horny epithelial debris which had accumulated at the follicle mouth. In some a thin atrophic hair, or a broken hair stump, projected from the summit of this cone; in others, the hair was wanting, having been shed or broken off flush with the surface. When dirt was present it tended to be incorporated with the material forming the cone, which then, on superficial examination,

resembled an ordinary sebaceous comedo. By degrees the conical projection flattened down into a scale, under which, on examination with a lens, a new developing hair could be seen coiled up like a watch spring. At this stage, also, the appearance on casual examination resembled that of a comedo. Later the flattened scale was shed, the new hair erupted and was seen to be growing from a pink recovering follicle. These changes were not simultaneous in all the follicles. When a patient was admitted to hospital it was the rule to find some follicles in the stage of conical swelling with the hair still present, some in the stage of flattened scale covering a new developing hair, and others in intervening stages of broken or shed hairs.

*Duration.*—The whole process took place gradually and was spread over many weeks. Owing to the fact that these changes caused no symptoms and never attracted the patient's attention their duration before admission could not be ascertained. Since, however, it was common to find some follicles in the stage of new developing hair when the patient came into hospital, it must be concluded that the abnormal process had commenced a month or even six weeks before. Under treatment recovery was gradual. As a rule, at the end of six or eight weeks, when the patients passed from observation, all the scales were shed, and young hairs could be seen growing from pink healthy follicles. It is probable that a further period of six to eight weeks elapsed before the normal condition became fully re-established, the whole process thus taking from four to six months in a marked case.

*Degree of recovery.*—Though it is possible that some few follicles were permanently destroyed, complete recovery must be the rule. All those which were watched in 1918 were seen to recover to the stage of commencement of a new hair, and no deficiency of leg hairs was ever noticed to follow the severe epidemic of scurvy from which the Serbians suffered in 1917.

#### *Causation and Value in Diagnosis.*

*The cause of hyperkeratosis of the follicle.*—The question was raised whether these keratotic changes could be due to a minute hæmorrhage having taken place into the deep part of the follicle, sufficient to impair its nutrition, but too small to be recognised as a hæmorrhage upon the surface. In the follicles of the petechial type the appearances were quite different. In these the follicle formed the centre of an intra-dermal hæmorrhage which showed as a flat round spot, 1 or 2 mm. in diameter, bright red in colour when recent, fading to a dull brown later. Although the hair of this follicle might be thin and atrophic or shed, there was never any heaping up of epithelium or keratosis, the spot remaining flat. Intervening types between the petechial and the keratotic were not seen, and the presence of hæmorrhage could never be demonstrated in one of the latter, so that it is safest to conclude that the keratosis was caused by a simple scorbutic impairment of the nutrition of the follicle.

Friction and irritation from dirt were taken into consideration as possible contributing causes and both dismissed. Friction seems to be ruled out by the frequency with which the pubic hairs were affected and by the fact that the infantry suffered as much as mounted troops. As regards cleanliness, the skins of these men were as well kept as those of any other troops on active service.

*Value in diagnosis.*—When this follicular hyperkeratosis had been recognised as occurring in the vast majority of cases of undoubted scurvy it was searched for in patients admitted for other diseases and at other seasons, as a result of which it was found that: 1. Follicular hyperkeratosis was unusual except during the scurvy season (January to June). When seen at other times it was usually in conditions involving marked wasting and debility, such as chronic dysentery, in which a deficiency of antiscorbutic vitamine might well have existed. 2. During the scurvy season, when the Serbian Army as a whole was suffering from deficiency of antiscorbutic vitamine, follicular hyperkeratosis was found to be present in a large proportion of patients admitted for other diseases. This was most striking in the case of men admitted to the surgical side for conditions which had not impaired the general health, such as gunshot wounds, herniæ, fractures, &c. Although these men might have no other signs or symptoms of the disease, we came to regard them as definitely scorbutic, and my surgical colleague, Major R. V.

Slattery, postponed operating upon them, whenever possible, until they had received some weeks of antiscorbutic treatment.

In consideration of these two points, and of the fact that most definite cases of scurvy, though admitted within a few days of the onset of symptoms, show a stage of keratosis which must have taken some weeks to develop, it seems obvious that the presence of this follicular hyperkeratosis may afford a valuable means of early diagnosis. I am under the impression that, given another scurvy epidemic among Serbian troops, it would be possible to pick out most of the men who were on the road to clinical scurvy by a brief inspection of the hair follicles of their legs, and to do this in the pre-symptomatic stage when preventive measures would still have time to succeed.

*The relation of hyperkeratosis to skin nutrition in general.*—Dr. A. Whitfield tells me that he recognises general dryness and roughness of the skin with follicular changes similar to those described above as occurring in all sorts of mal-nutritional states, but most commonly in association with wasting. He regards it as a general stagnation process which shows most in the follicles, the cells being incompletely matured and consequently cohering to make a flake which is shed en masse, instead of by individual cells as an imperceptible process.

As noted by Johnson Smith,<sup>2</sup> wasting—that is to say, simple loss of fat and muscle—does not occur in uncomplicated scurvy. Certainly some of my cases which showed these follicle changes in marked degree were amongst the finest specimens of physical manhood I have ever seen; and, excluding complicating factors such as dysentery and malaria, the majority were above rather than below the average of physical development. In the case of these Serbians it seemed that nothing was lacking save antiscorbutic vitamine—a fact which invites speculation concerning the pathogeny of the similar skin condition which occurs in other malnutritional states.

It is to be remembered that with our modern habits of cooking the intake of antiscorbutic vitamine of the average individual falls considerably below the ration which was intended by nature.

#### *Conclusions.*

1. Follicular hyperkeratosis occurs in the vast majority of cases of clinical scurvy.

2. In a large proportion of cases it formed the first recognisable sign of the scorbutic tendency, and would have enabled a diagnosis to be made before the onset of symptoms.

3. It is similar in appearance to the hyperkeratosis of follicles which occurs in other malnutritional states.

4. It appears to be due to altered nutrition of the follicle produced by simple deficiency of antiscorbutic vitamine.

I am indebted to Dr. Whitfield for information concerning follicular hyperkeratosis in general malnutrition, and to Miss Ahern for careful clinical notes of the cases quoted.

**CENTENARIANS.**—Mr. W. C. Vivian died on August 29th at his residence, Reskaldinnick, Camborne. He celebrated the one hundredth anniversary of his birthday on June 6th last.—Miss S. E. Selden, daughter of the late Mr. W. C. Selden, M.R.C.S., of Melksham, died recently at Bath. She was born in Bath on Feb. 3rd, 1819.

**GUY'S HOSPITAL WAR MEMORIAL.**—The fund for the Guy's Hospital Memorial will be closed at the end of the present month and a general meeting of the subscribers will be held in October to decide upon the form or forms which the memorial shall take. The first charge on the fund will be the education of the children of Guy's men who have fallen in the war, should such help be required, as well as assistance to widows and to Guy's men permanently disabled. Fortunately the help required in this direction will not demand much of the fund, and it is proposed to devote a portion of the subscriptions to a War Memorial Clinical Ward, the adornment of the Dining Hall of the College, and the formation of a nucleus for endowment of a Dental Research Scholarship.

## FOREIGN BODIES IN THE ŒSOPHAGUS AND RESPIRATORY PASSAGES.

### REMARKS ON THE DANGERS ARISING FROM THEIR IMPACTION AND SOME DIFFICULTIES WHICH MAY BE MET WITH IN THEIR REMOVAL:

A PLEA FOR THE ABOLITION OF THE COIN-CATCHER, THE BLIND USE OF THE BOUGIE AND PROBANG, AND THEIR REPLACEMENT BY THE DIRECT ENDOSCOPIC METHODS OF EXTRACTION.

By IRWIN MOORE, M.B., C.M. EDIN.,  
SURGEON TO THE THROAT HOSPITAL, GOLDEN SQUARE, W.

It is very well known that many obsolete methods of treatment persist in various departments of medicine and surgery at the present day and are still described in recent text-books. In the case of foreign bodies in the air- and food-passages the use of such out-of-date instruments as the coin-catcher, bougie, and probang still persists, much to the chagrin of the specialist, whose preaching of the dangers and risks of such unsurgical methods of treatment by blind working in the dark appears in many instances to have passed unheeded. Though old habits die hard, yet it appears incomprehensible how such procedures can still continue in the face of the accumulated experience and repeated warnings of the entire body of laryngologists. Since improvement in the "direct vision" method of per-oral endoscopy has placed at our disposal the more exact means of treating such cases, one would have thought that the coin-catcher at least would have been banished from our instrumentarium once and for all. The following cases, however, show that this haphazard and dangerous instrument is still being used, often with disastrous results.

#### THE BLIND USE OF THE COIN-CATCHER AND ITS DANGERS.

*A Halfpenny accidentally Swallowed and Impacted in the Œsophagus for Six Days, Removed by the Œsophagoscope, after Repeated Attempts with a Coin-Catcher had Failed.*

Though this case is only one of many others, in which coins and various foreign bodies have been successfully removed by endoscopic technique, yet it would appear to be of sufficient interest to merit publication in view of the importance of the discussion to which it gave rise when reported at a meeting of the Laryngological Section of the Royal Society of Medicine.<sup>1</sup>

On August 8th, 1915, at 4 P.M., a little girl, aged 4 years, was taken to a suburban general hospital, having swallowed a halfpenny at mid-day whilst playing with it in her mouth. With the exception that she had been sick three or four times there were no other symptoms. Examination showed no difficulty in breathing and as the patient appeared to be quite comfortable she was sent home. The following morning she was

in front of it. (Fig. 24.) On withdrawal of the tube and again passing it carefully down the posterior wall the coin was easily located and removed without any difficulty with forceps. The child returned home next day, and no complaints were afterwards made of soreness of the throat, difficulty in swallowing, or any other symptom. Fortunately, in this case no damage had been done to the œsophageal wall by the coin-catcher.

The case gave rise to considerable discussion at the above meeting in connexion with the dangers of this old-fashioned and out-of-date instrument. Mr. D. R. Paterson referred to the case of a child who had been sent to a general hospital with a coin in its œsophagus, and because a coin-catcher "failed to bring anything away" the child was sent home. It was not until 18 months later, when "tracheal symptoms" arose, that the case came under his notice. The coin was discovered in the gullet by œsophagoscopy and was safely removed. He remarked that these cases were now common, and he thought it was time that the authorities at general hospitals recognised that the direct method was the proper one, and that

FIG. 1.—Skiagram showing a halfpenny impacted in the œsophagus of a child aged four years. Posterior view.

such cases should not be submitted to a coin-catcher. Sir William Milligan associated himself with Mr. Paterson's remarks. He thought that hospitals should give definite instructions to house surgeons not to use the coin-catcher, and that it was lamentable the state the œsophagus was brought into sometimes by the inexperienced trials at removal of foreign bodies. He had several times seen fatal cases as the result of the wall of the œsophagus being torn by the coin-catcher. If these cases were at once sent to the proper department the right method would be used. He suggested that a

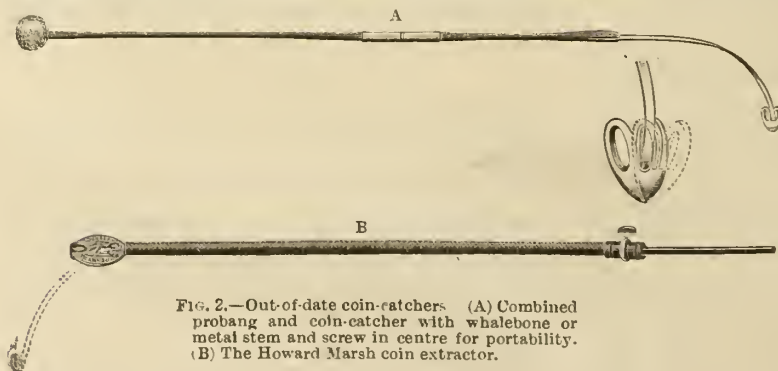

FIG. 2.—Out-of-date coin-catchers. (A) Combined probang and coin-catcher with whalebone or metal stem and screw in centre for portability. (B) The Howard Marsh coin extractor.

FIG. 3.—Semi-diagrammatic view of a coin impacted against the posterior wall of the œsophagus, leaving sufficient room in front for a coin-catcher to pass up and down without touching the coin.

brought back to the hospital as she had been sick during the night, and was unable to swallow anything but liquid food. On this occasion she was admitted and X rayed by Dr. David Arthur, when the coin was distinctly seen to be impacted in the œsophagus at the level of the seventh cervical vertebra—i.e., just below the cricoid cartilage. (Fig. 1.) Three or four attempts to extract the coin with a coin-catcher (Fig. 2) without a general anæsthetic failed. It was not till six days later that it was considered advisable to send for a laryngologist, and the writer was asked to attend. The child was placed under chloroform anæsthesia, an endoscopic tube of 10 mm. diameter was passed into the œsophagus, but the coin could not at first be seen, since the tube had passed down

resolution should be framed and forwarded to the various teaching hospitals in this country. Mr. W. Howarth related a case which occurred at his hospital, illustrating Sir William Milligan's remarks, where attempts were made to extract a halfpenny from a child's œsophagus by means of a coin-catcher. The child bit the coin-catcher, broke off the end, and this was swallowed. It became impacted in the pylorus and had to be removed by laparotomy, and the coin, which remained impacted in the œsophagus, was removed by the direct method. Since this occurrence the coin-catcher had

<sup>1</sup> Proc. Roy. Soc. Med., 1915, ix. (Laryngol. Sect.), pp. 39-41

FIG. 4.—The cricoid-pharynx and upper part of oesophagus seen from behind. A portion of the posterior wall has been removed to show the coin-catcher which has caught a coin, but on withdrawal has itself been caught under the posterior inferior edge of the cricoid cartilage, so that neither the coin-catcher nor the coin can be extracted.

2 years, who had a penny lodged in the oesophagus five days previously and where forceps had been blindly passed without an oesophagoscope, which he considered an "utterly unjustifiable procedure." When seen "the temperature was 104° and the pulse uncountable, sloughs were being vomited, and the child was sinking away in the profound shock of a traumatic oesophagitis. Its death

been banished from the casualty department at his hospital. Dr. F. de Havilland Hall expressed his opinion that it was very desirable that the members of the Section of Laryngology should draw up a communication and send it to the members of general hospital staffs—that the time had come for pronouncing that the direct method should be employed in these cases instead of using the coin-catcher.

*Some Reported Cases showing the Disastrous Results following Attempts at the Blind Extraction of Foreign Bodies.*

The following are a few of many cases reported in the medical press which are here referred to in order still further to emphasise the disastrous results of the blind probing in the dark with forceps, the coin-catcher, or probang:—

Chevalier Jackson<sup>2</sup> (Philadelphia) mentions that he had seen a child, aged

FIG. 5.—The same in sagittal section. The coin is seen lying in the posterior half of the coin-catcher, whilst the anterior portion has been caught under the lower projecting edge of the cricoid cartilage.

Thomas Guthrie<sup>4</sup> (Liverpool) reports a case in which a halfpenny was impacted in the oesophagus and a previous unsuccessful attempt at removal with the coin-catcher failed. On examination with the oesophagoscope the coin was found to have been forced upwards and buried under the mucous membrane at about the level of the cricoid. Removal was performed by tearing through the mucous membrane, but recovery was fortunately uneventful.

E. D. Davis<sup>5</sup> supplies the following notes of two cases not yet recorded:—(1) A girl, aged 4½, swallowed a halfpenny, which became impacted in the gullet immediately below and overlapped by the lower edge of the cricoid cartilage. Several unsuccessful attempts were made

FIG. 6.—This diagram shows the disadvantageous and strained position commonly employed for the passage of endoscopic tubes through the buccal cavity, pharynx, and oesophagus, with over-extension of the head and neck, causing anterior curvature of the cervical vertebrae; it also shows the faulty position of the tube in the middle line of the mouth and in contact with the incisor teeth.

was really due to the absolute ignorance of the family physician, who had never heard of oesophagoscopy and its safety in trained hands."

Logan Turner<sup>3</sup> (Edinburgh) refers to a case where a halfpenny had remained in the oesophagus for only one week, and the patient died as a result of the injury caused by the old-established method used for the removal of the coin, and not from the presence of the coin itself.

to remove it by experienced and skilful surgeons accustomed to the use of the coin-catcher. The coin was finally removed without difficulty by oesophagoscopy. (2) Report of an inquest in the lay press on a boy where the coin-catcher was used to extract a penny. The coin-catcher broke and the child died with the penny and piece of the coin-catcher fixed in the gullet.

Norman Patterson<sup>6</sup> gives the particulars of an unreported case which occurred at one of the London hospitals. A child, aged 4 years, had a

<sup>5</sup> Personal communication to the author.

halfpenny impacted in its œsophagus at the level of the cricoid cartilage—as shown by X rays. During attempts to move it with the coin-catcher the basket portion broke off from the stem and passed into the stomach. Both coin and coin-catcher had to be removed the same evening by gastrotomy. The coin-catcher employed had been in use at this hospital for 20 years, and had become weakened by rust and old age.

G. L. Richards<sup>7</sup> (Fall River, Mass.), at a meeting of the American Laryngological Association in 1909, in describing the coin-catcher as almost obsolete, mentions that a child of 2 or 3 years of age was brought to one of his colleagues with a coin in the œsophagus, and he used the coin-catcher. After catching the coin and trying to remove it, he found this was impossible on account of urgent symptoms of suffocation. He had to do a tracheotomy first, and was then able, but

Donald Armour<sup>8</sup> refers to the case of a boy, aged 5 years, who swallowed a coin, which was seen by X rays lodged in the pyriform fossa. A house surgeon passed a coin-catcher and engaged the coin, but on traction being made to remove it the coin-catcher broke off at the junction of the metal part with the whalebone handle. The portion of the coin-catcher, 5 inches in length, passed down and lodged in the lower end of the œsophagus. The coin was easily extracted through the mouth with a pair of forceps, whilst it was necessary to perform laparotomy and gastrotomy in order to remove the portion of the coin-catcher.

Gordon King<sup>10</sup> (New Orleans, U.S.A.) protests against the indiscriminate use of the coin-catcher, which he says may be the cause of serious injury to the œsophagus. He cites a case reported by Schileau

FIG. 7.—This diagram shows the correct position for the easy insertion and passage of endoscopic tube into the œsophagus when the upper two-thirds are under examination.

FIG. 8.—The same when the lower third of the œsophagus is under examination: the head being lowered by means of the movable table flap, the axis of the endoscopic tube is brought into line with and parallel to the œsophagus in the horizontal plane.

with difficulty, to remove the coin-catcher, since it had got caught under the cricoid cartilage (Figs. 4 and 5 have been specially drawn for the writer to illustrate how this danger can occur).

Chevalier Jackson<sup>8</sup> (Philadelphia), in a discussion which followed, said he was sorry to say the coin-catcher was not an obsolete instrument. A patient was brought to his hospital a few weeks previously with a penny in the œsophagus. A coin-catcher had been previously passed down to take out the penny, the position of which was demonstrated by a radiogram, but the coin-catcher entered the trachea and on being drawn out had torn out the inside of the larynx. The child was in a very serious condition. It took him but a moment to remove the penny safely and easily by aid of the œsophagoscope.

of death occurring from tearing through the œsophageal wall in efforts to extract a coin. He also cited another case reported by Felizet, where the basket end had been broken off and lodged in the gullet with the coin.

#### *Frequency of Lodgment of Foreign Bodies.*

Statistics show that the lodgment of foreign bodies in the air and food passages is much more common than generally supposed, especially amongst children, on account of their habit of placing things in their mouth, and these foreign bodies are exceedingly likely to make their way into the

FIG. 9.—Approach to the lower sphincter orifice of the pharynx (closed) as seen through Hill's 18 mm. diameter oesophagoscope.

FIG. 10.—The lower pharyngeal orifice partially open. Note the alteration in the shape of Killian's lip. The pharyngo-oesophageal junction and the mouth of the oesophagus is out of sight in deep shadow. Note also the pharyngeal "lip" forming a distinct ledge posteriorly. Hill has pointed out that Killian inaccurately described this lip as forming the posterior boundary of the mouth of the oesophagus.

FIG. 11.—View of the cervical and upper thoracic oesophagus after passage of the tube through the lower sphincter orifice of the pharynx.

oesophagus. Though in some cases a coin when it has entered the oesophagus may safely pass through the alimentary tract and be evacuated without causing any symptoms, few foreign bodies, if inspired into the respiratory tract, are voluntarily expectorated. It has been shown by innumerable cases that the risk of the sojourn of a foreign body is greater than the risk of early per-endoscopic removal. Therefore when the fact of the accidental swallowing of a foreign body is recognised no time should be unnecessarily lost before it is sought for and removed, since if not removed as soon as possible it may give rise to local irritation, oedema, septic infiltration, ulceration, perforation, and death.

#### Pre-endoscopic Days.

A. E. Durham<sup>11</sup> refers to Adelman's<sup>12</sup> analysis of 314 untreated cases of foreign bodies in the oesophagus during the pre-endoscopic days, in 109 of which cases fatal results ensued. In 31 of the fatal cases death was due to perforation either of the heart, aorta, or one of the great vessels; in 43 to lesions of the respiratory organs; and in 25 to ulceration of the oesophagus and septic inflammation set up in the neighbouring parts.

Chevalier Jackson<sup>13</sup> states that 105 deaths were recorded in North America alone in five years from foreign bodies in the air and food passages, from ill-advised efforts at removal—e.g., blind groping with forceps or bougies. McKinney<sup>14</sup> adds: "There are also many more unrecognised and unreported cases which would increase the high mortality rate."

#### Brilliant Results of Endoscopy.

The introduction of straight endoscopic tubes has placed at our command the means by which removal of foreign bodies from the air and food passages can now be efficiently carried out by

FIG. 12.—Coin impacted partly in the cervical pharynx and partly in the cervical oesophagus (after Guisez).

expert endoscopists under direct vision by forceps with hardly any risk to the patient; and in this way the death-rate has been greatly reduced so that many valuable lives have been saved.

Chevalier Jackson<sup>15</sup> gives the mortality and results of bronchoscopy in the removal of foreign bodies from the air passages during recent years as ranging from 5.3 to 1.7 per cent., while that of oesophagoscopy as 3 per cent. to nil. He states that in his own clinic in 182 cases of bronchoscopy the foreign body was removed in 177 cases, whilst in 203 cases of oesophagoscopy the foreign body was removed in 198 cases, and escaped downwards in 8. There were only 4 deaths, 1 due to chronic disease of the kidneys, the other 3 the result of previous laceration due to improper attempts at extraction.

Friedberg<sup>16</sup> (Chicago), from the analysis of 50 cases of foreign bodies in the oesophagus since the introduction of endoscopic methods, shows that the age period varies from 7 months to 63 years, but that the greater number—viz., 42—occurred between the ages of 7 months and 10 years, 13 of which were between 1 and 2 years of age. Of the 50 cases of foreign

FIG. 18.—The thoracic oesophagus seen during the inspiratory stage more widely open and its lumen more circular than in the cervical region.

bodies it is interesting to note that 29 were coins or disc-shaped bodies, and that 40 were impacted below the crico-pharyngeus and only 4 above—i.e., in the deep pharynx. Successful extraction by endoscopy occurred in 47 cases and only 2 became dislodged and passed into the stomach. The only fatal cases amongst these 50 foreign bodies was in that of an impacted coin in which considerable traumatism had previously been caused by indirect methods, resulting in death from infection following a trachea-oesophageal fistula.

That the medical profession in general have not yet fully recognised the dangers which may accrue from the swallowing of foreign bodies, nor realised the brilliant results obtained by oesophagoscopy and bronchoscopy methods, is shown by many cases of death reported in the lay press. For example,

in the same week as the writer's case previously referred to there was reported<sup>17</sup> the "Death from misadventure" of a child aged 11 years, who, while playing with her father and performing a conjuring trick, accidentally swallowed a penny which stuck in its throat. Attempts on the part of the father to remove the coin having failed, the child was taken to a cottage hospital, where it died some days later of "septic poisoning." At the inquest it was stated that there was a difficulty in obtaining the services of an X ray expert to locate the coin! Though the use of the Roentgen rays may prove of great service both in settling the presence of a foreign body and in determining its exact position, yet if it is not available there is no reason why the endoscopic tube alone should not be used to locate and extract a foreign body so long as it is passed under direct vision. The X rays should only be considered as an accessory in endoscopic work and not as an absolute necessity. It is important to remember, however, that a button if made of vegetable ivory and some kinds of vulcanite may not be revealed by X rays. Again, "Death by misadventure" was the verdict<sup>18</sup> recently given at another of the many inquests on children who have died from swallowing foreign bodies—in the case of a two-year-old child who swallowed a halfpenny. The coin perforated an internal organ and set up inflammation of the lungs. A more correct verdict, the author suggests, would have been "Manslaughter" for neglecting to send for an experienced endoscopist.

*The Danger of Foreign Bodies, with reference especially to Coins in the Œsophagus and some Difficulties which may be met with in their Extraction by Endoscopy.*

Since this article is mainly concerned with the use and abuse of the coin-catcher, reference has been chiefly confined to cases of coins and allied circular bodies.

**Œsophageal measurements.**—The œsophagus is 10 inches long in the adult. It commences just below the lower border of the cricoid cartilage—i.e., below the lower sphincter orifice of the pharynx, its opening or mouth being in the adult about 6 inches distant from the upper incisor teeth. From the latter to the crossing of the aortic arch the distance is 10 inches, whilst to the level of the diaphragm it is 16 inches. These measurements vary somewhat in adults, and in children may be reduced to one-half.

The so-called mouth of the œsophagus is often described as a transverse slit bounded in front by the lower border of

FIG. 25.—The same, showing commencing folding of the swollen post-œsophageal mucosa over an impacted coin. The anterior wall is seen well distended by the endoscopic tube.

FIG. 26.—The same, showing a later stage of folding of the swollen post-œsophageal mucosa over an impacted coin, which is securely grasped, and almost completely hidden from view.

the cricoid cartilage and behind by the vertebral column, but, as emphasised by William Hill,<sup>19</sup> this is usually confused with the lower sphincteric orifice of the pharynx.

The average measurements of this orifice in the adult cadaver are 23 mm. in the transverse and 17 mm. in the sagittal diameter. The average transverse diameter of the unstretched œsophagus in the living adult is 25 mm. (1 inch) all the way down; the antero-posterior diameter varying from 19 mm. ( $\frac{3}{4}$  inch) at the cricoid to 25 mm. (1 inch) at the cardia. The œsophageal lumen, however, is capable of much greater distensibility both in the infant and adult, as shown by the passage of circular foreign bodies—e.g., coins, buttons—of much larger diameter.

D. R. Paterson<sup>20</sup> (Cardiff) has safely removed from the œsophagus of a soldier by means of a 20 mm. tube the disc of a bully beef tin measuring 35 mm. ( $1\frac{3}{8}$  inch)—i.e., rather larger than a half-a-crown, which was impacted at the level of the sternal notch, whilst Whale<sup>21</sup> had previously reported an exactly similar disc with the same diameter which he was obliged to remove by œsophagotomy.

Luschka<sup>22</sup> reported a post-mortem case where the œsophagus was dilated to 46 cm. in length ( $18\frac{1}{2}$  inches) and 30 cm. (12 inches) in circumference at its widest part—i.e., a diameter of  $3\frac{1}{2}$  inches. This case is interesting in so far that it shows to what an enormous extent the œsophagus may become pathologically dilated.

*The chief sites of impaction of foreign bodies in the œsophagus and adjacent portion of the deep pharynx.*—

<sup>18</sup> Ibid., May 19th, 1918.

above the lower sphincter orifice of the pharynx. 2. At the junction of the pharynx and oesophagus, being partly in each. 3. The loose cervical portion of the gullet entirely below the sphincter. 4. At the constriction in the thoracic gullet where the left bronchus crosses it. 5. According to Stark there is a constriction where the aorta crosses it. 6. At or just above the phrenic level where there is narrowing of the gullet.

*The Direct Endoscopic Method of Extraction of Foreign Bodies.*

In examining the oesophagus it is advisable to employ as large a tube as possible, since not only a more extensive view of the field may be seen, but also there is more room for the manipulation of instruments, and consequently more successful results may be obtained with celerity and certainty, especially when dealing with foreign bodies. Experience has shown that much larger tubes than those first employed may be used with safety and without causing traumatism, provided the operator has acquired the necessary skill and technique.

While Chevalier Jackson employs endoscopic tubes of 7 mm. in infants and 10 mm. as the largest size in adults

FIG. 27.—Brunings's endoscopic tube with spatula-shaped extremity.

FIG. 28.—Killian's endoscopic tube with plane (i.e., non-bevelled) distal extremity.

FIG. 29.—Semi-diagrammatic sectional view of the oesophagus showing how a small-sized endoscopic tube may override a loose fold of the posterior wall, which may conceal and partly cover a foreign body—e.g., a coin. The foreign body is consequently out of the line of vision.

FIG. 30.—The same, showing a large tube about to negotiate and obliterate a fold. The lower edge of the coin is here seen in the line of vision.

FIG. 31.—The same, showing a large-sized tube stretching the oesophageal walls, as it descends, so obliterating any folds which may be present. In this way the upper edge of a coin lying on the posterior wall becomes tilted forward towards the centre of the advancing tube and its upper edge is easily seen and seized by forceps.

for oesophageal work, Brunings<sup>23</sup> uses tubes that are larger and considers that the largest should not exceed 14 mm. though he has opened an expanding tube to 30 mm. (1 3/16 inch). D. R. Paterson<sup>24</sup> has shown that much larger tubes of 18 and 20 mm. diameter may be passed with safety, and are especially to be commended in the removal of large foreign bodies. His opinion has been confirmed by William Hill, who has used and advocated larger tubes up to 18 mm. diameter for some years.

When using a small or medium-sized tube its distal end has to be moved about from side to side and orientated in order to thoroughly expose the oesophageal walls and foreign bodies are likely to be overlooked, whereas the passage of a large tube circular on section, or, as recommended by Mosher, oval on section, causes distension of the walls, and as the tube is advanced any transverse folds in the walls are obliterated (Figs. 29, 30, 31), and the oesophagus may be seen standing open for some inches ahead of the tube. The tubes should never be passed except under the direct vision of the eye and no force whatever should be used. It is harder to insert a large tube past the cricoid, but the difficulty is easily overcome if the patient is placed in the proper posture, so that the buccal cavity and neck are in a straight line with the thoracic portion of the oesophagus.

*Position of Patient for Oesophagoscopy.*

The dorsal recumbent position with slight extension of the head at the occipito-atloid joint is the correct position for the easy insertion of the tube. (Fig. 7.) This position was first described by William Hill in 1912, who showed that the axis of the oesophagoscope more nearly approaches an angle of 45° with the horizontal when the upper two-thirds of the gullet are under examination. (Fig. 7.) He points out that in endoscopy of the lower fourth of the oesophagus the axis of the tube becomes more or less horizontal. (Fig. 8.) If the lumen of the tube is not seen several inches ahead we are not in the right axis, and the head may require raising or lowering, according as to whether the oesophagoscope is up against the anterior or posterior wall.

The patient lies in the natural recumbent position on the table—the head is extended by placing the finger in the mouth and making traction on the upper alveolar region horizontally away from the head of the table; this extends the head at the occipito-atloid joint without interfering with the position of the cervical spine which slopes gently downwards. This extension of the head without altering the curve of the cervical and upper dorsal spine serves to bring the axis of the bucco-pharyngeal cavity into line with that of the upper half or two-thirds of the oesophagus, and it is then an easy matter to pass an endoscopic tube and all obstruction is avoided (Hill),<sup>25</sup> whereas if the tube is passed in the middle line it will hitch against the teeth, also the arytenoid cartilages or posterior surface of the cricoid plate. (Fig. 6.) The head can be raised or lowered as necessary during the passage of the tube by means of a movable table flap. This is a much better posture than the Rose position

<sup>23</sup> Direct Laryngoscopy, Bronchoscopy, and Oesophagoscopy, 1912, p. 237.

<sup>24</sup> Proc. Roy. Soc. Med., 1916, ix. (Laryngol. Sect.), p. 41.

<sup>25</sup> Journ Laryngol., Rhinol., and Otol., 1916, xxxi., p. 107.

or the modified Rose position of Boyce and Jackson, where the posterior part of the vertex and occiput is hanging over the end of the table and occupies a lower plane than the trunk—causing anterior curvature of the cervical vertebra and over-prominence of the sixth cervical vertebra—so obstructing the passage of the tubes. To get over the difficulties of this position some operators employ an assistant to raise or lower the head while it is extended—at the occipito-atlantal joint—this not only brings the air passages into line, but also the cervical vertebrae parallel to the œsophagus in the horizontal plane. This latter is termed the Boyce position, and is used by Chevalier Jackson.

*Introduction and Passage of the Œsophagoscope.*

The tube should be inserted through the right angle of the mouth, advancing by the right side of the tongue through the buccal cavity and pharynx to the right pyriform fossa, then through the hypo-pharynx or post-cricoid pharynx to its lower sphincteric orifice. This orifice, as previously stated, has been wrongly referred to in the past as the mouth of the œsophagus, and is often described as a transverse slit, bounded in front by the lower border of the cricoid cartilage and behind by the vertebral column, but, as so frequently emphasised by William Hill, this is really the lower sphincter orifice of the pharynx, and the mouth of the œsophagus is situated immediately below.

Coins or similar circular bodies, such as large buttons or discs, when accidentally swallowed, are not always easy to find. They generally enter the œsophagus flat, being so directed by the transverse shape of the lower sphincter orifice of the pharynx (Fig. 9), and almost invariably retain their original position as they descend—i.e., lie flat against the vertebral column, so that when they become impacted they are found lying against the posterior wall (Figs. 23 and 24) or in a band or recess of the œsophagus—anywhere from the cricoid to the cardia (Figs. 25 and 26),

FIG. 32.—Shows a halfpenny encysted in the post-œsophageal wall of a child aged 1 year and 10 months. The dotted circle represents the position of the buried coin. In the specimen the trachea and anterior wall of the œsophagus have been slit open from the front exposing the coin lying in its bed. The dotted line represents the buried circumference of the coin. Note the irregular folds of the œsophageal wall surrounding and nearly completely hiding the coin, only 1/5 of the centre being seen. The remarkable distensibility of the œsophagus at this age is also well seen. (Mr. Jewell's case, from a life-sized drawing specially made for the author, from the specimen, by kind permission of Mr. Jewell.)

and forceps must open antero-posteriorly in order to grasp them. The exact opposite occurs when they are aspirated into the trachea, the antero-posterior position of the vocal cords causing them to enter the trachea edge on—i.e., antero-posteriorly—in which position they are generally found.

The appearance of the œsophagus, as seen through the œsophagoscope, not only varies somewhat in different

FIG. 33.—Shows portion of halfpenny which has perforated the post-œsophageal wall into the posterior mediastinum. This illustration is from a photograph showing posterior view of Fig. 32. (Mr. Jewell's case.)

individuals, but also according as to whether a large or small tube is used in the examination. It also varies according to the position of the tube—i.e., of its distal end—for at one time the lumen may appear centralised (Fig. 14), whilst at others it may be seen in the anterior part of the field with a considerable area of the posterior wall showing posteriorly (Fig. 15), or vice versa. That is to say, in examination of the œsophagus we necessarily obtain a composite view. When an endoscopic tube is passed down into the hypo-pharynx or cricoid pharynx, the lower sphincter orifice is seen to be closed and is represented by a slit consisting of an anterior and posterior lip, the latter being more prominent. (Fig. 9) A short delay may occur here on account of spasm. There is a depression behind on the upper surface of the posterior lip (of Killian) against which the posterior edge of the tube may rest and pressure on which may increase the sphincteric spasm and cause the advancing tube to be held up. By gentle pressure downwards and anteriorly the spasm becomes relaxed and the sphincter opens (Fig. 10), allowing the examining tube to enter the cervical œsophagus. This entrance is the narrowest part of the œsophagus in the living subject.

Figs. 9, 10, 11 represent composite extended endoscopic views of the lower pharynx and œsophagus, drawn from life, by orientation of the distal end of the largest calibre œsophagoscopic tube (18 mm. diameter).

A coin impacted below the sphincteric orifice may have its upper edge hidden by the projecting forward of the posterior pharyngeal wall—i.e., by Killian's lip. This is due to the spasmodic contraction of the lower sphincter of the pharynx—i.e., the lower horizontal bundle of fibres of the inferior constrictor muscle (crico-pharyngeus), which, as before stated, is situated just above the œsophageal mouth. As the endoscopic tube enters the sphincteric orifice it tends to ride down over this lip and may easily pass in front of a foreign body which remains out of the line of vision. Chevalier Jackson in his latest work "Per-oral Endoscopy," 1915, shows an œsophagoscopic view of a coin wedged in this

position, with forceps retracting the subjacent cricopharyngeal fold, preparatory to removal of the coin. (Plate, iii., No. 10, p. 708.)

After passing through the pharyngeal sphincter the tube enters the cervical oesophagus, the lumen of which in the normal condition may be seen to contract and expand more or less with the respiratory movements—i.e., opening during inspiration (Fig. 13) and closing during expiration (Fig. 14), the latter having the appearance of a small dark rosette which, according to the position of the tube, may be either centrally or peripherally situated. (Figs. 14 and 15.)

Below the top of the sternum as far as the cardiac orifice of the stomach, the expansion and contraction of the thoracic oesophagus is usually found to be more marked than in the cervical region. In consequence of opening wider during inspiration (Fig. 18) it may be possible to see ahead for some distance; especially is this the case when a large tube is employed, for the movements of the oesophagus are less active because of stretching of its walls, and the oesophagus stands open for a distance of an inch or two beyond the end of the tube before it narrows down to the customary expiratory contracture (central rosette).

In the thoracic region the closure of the oesophagus is not, as a rule, so complete as it is usually in the cervical region (Figs. 14 and 19), when tubes of moderate calibre are employed.

These oesophagoscopic views have been carefully drawn from life, during the examination of a large number of cases and with various sized endoscopic tubes. I am much indebted to my friend, Dr. William Hill, for material and for assistance in my endeavours to attain pictorial correctness.

When a coin has passed the pharyngo-sphincteric constriction there is a tendency for it to be caught and impacted in the loose and collapsed walls of the cervical oesophagus before it reaches the second constriction caused by the crossing of the left bronchus.

James E. Logan<sup>26</sup> (Kansas, U.S.A.) states that foreign bodies usually lodge at the second constriction of the oesophagus, and there is no doubt that this is the commonest situation in children.

Scanes Spicer<sup>27</sup> says "It is remarkable that foreign bodies such as coins should pass the lower sphincter orifice of the pharynx and yet get lodged in a wider part of the gullet just below. It was, no doubt, the prominence of the first dorsal vertebra behind the manubrial notch in front, and the first ribs externally, which, forming the superior orifice of the thorax, provided a sufficiently narrow channel at the best of times when packed with the trachea, gullet, thyroid gland, great vessels, nerves, and lymphatic glands."

If a coin becomes so impacted, and this applies equally to the thoracic oesophagus, on approaching it with the endoscopic tube the normal opening and closing of the lumen is seen to have disappeared, and its place taken by a dark horizontal slit (Fig. 22) somewhat similar to that seen at the pharyngo-sphincter constriction. (Fig. 9.) This dark slit is caused by the coin stretching and holding apart the oesophageal walls. When this is observed we know that the coin is close by, and a careful search should be made especially along the posterior wall. The upper edge of the coin may be hidden by a folding over of the swollen or collapsed mucous membrane of the posterior and lateral walls (Figs. 25 and 26), so that it is possible for the examining tube to ride over and slip past it without it being observed or even touched by the tube, just as may occur at the pharyngeal sphincter. Especially is this the case when a tube with a spatula extremity is used (Fig. 27), the upper edge of the coin being either imperfectly seen or not seen at all, and it is therefore impossible to grasp it with forceps. When, however, a tube with plane or non-bevelled extremity is used (Fig. 28), and of the largest size that can be passed with safety, as it descends it straightens out any loose folds, thus tilting the upper edge of the coin forwards and causing it to become more central and to appear across the opening of the tube, when it can be easily seized.

This was well exemplified in a case where I was recently asked to assist a colleague.

A child, aged 1 year and 3 months, swallowed a bone button the same size as a halfpenny—i.e., 25 mm. diameter. It had been impacted for three days in the cervical oesophagus and its upper edge was so covered by the loose folds of the posterior wall that it was found impossible, after many attempts with a spatula-shaped tube, to see the coin properly and to grasp it. The following day a short tube of 12 mm. diameter, with non-bevelled extremity was used, with the desired effect of stretching out the folds, so that the upper edge of the button at once pre-

sented in front of the tube and was easily removed. A stricture caused by a foreign body may require to be dilated before the foreign body can be reached and removed.

In some cases the swollen and oedematous mucous membrane may cover an impacted coin so as to hide it not only partially but completely, or the coin may become encysted.

Tappey<sup>28</sup> reports the case of a child, 2½ years of age, with a silver quarter of a dollar in the oesophagus. The presence of the coin had caused hyperplasia of the wall in which the coin had become embedded. It was removed by oesophagotomy.

Halsted<sup>29</sup> (Syracuse, N.Y.) refers to the case of a child, aged 5 years, who had swallowed a penny during infancy. It was found encysted in the post-oesophageal wall, and was only released after curetting the wall through the endoscopic tube.

Munro<sup>30</sup> mentions a case in which a halfpenny was retained in the oesophagus of a boy for three years. After death from consumption the coin was found closely embraced by the gullet.

Jewell<sup>31</sup> reported the very interesting case of a child, aged 22 months, who swallowed a halfpenny ten days before admission to hospital, and it became impacted against the post-oesophageal wall. The coin was located by X rays just below the sterno-clavicular articulation, but all attempts to remove it both by forceps and hooks failed, nor could it eve-

FIG. 34.—Skiagram showing lateral view of a farthing impacted partly in the cricoid-pharynx and partly in the cervical oesophagus of a child aged 2 years.

be moved from its bed. Death occurred on the thirteenth day after the swallowing. Post mortem examination showed that the coin had become almost completely embedded in the post-oesophageal wall, the circumference of the coin and four-fifths of its anterior surface being enveloped by folds of swollen mucous membrane (Fig. 32), and that it had caused death by perforation into the posterior mediastinum. (Fig. 33.)

Kent Hughes<sup>32</sup> had a case in which a halfpenny was swallowed by a child five months previously, and the patient was brought to a children's hospital on account of broncho-pneumonia. There was a history that something had been swallowed, and X rays showed a halfpenny in the posterior mediastinum, and it had ulcerated through the right posterior wall of the oesophagus. He managed to remove it by cutting away part of the clavicle and two ribs. The child, however, died of the pre-existing broncho-pneumonia.

McKinney<sup>33</sup> (Memphis, U.S.A.) reports the case of a girl, aged 2 years, who swallowed a button (the same diameter as a halfpenny) three or four days previously. Fluids only could be swallowed and with great difficulty. It was impacted just above the sternal notch and caused considerable congestion and swelling of the oesophageal mucosa followed by oedema of the glottis and death.

Friedberg<sup>34</sup> (Chicago) reports the case of a boy, aged 3, from whom a nickel and two pennies (U.S.A.) were removed from the oesophagus at the same time, as they were all stuck together. A foreign body may also be hidden from view by particles of impacted

<sup>27</sup> Discussion on Tilley's case of a penny removed from the gullet in a young girl aged 14. Proc. Roy. Soc. Med., 1910, iii. (Laryngol. Sect.), p. 135.

food—e.g., H. J. Davis<sup>35</sup> reported a case where a penny was impacted in the oesophagus of a woman aged 25. The patient was unable to swallow anything for four days. The coin was hidden by grape skins which obscured its view, and was firmly grasped by the oesophageal wall. After removal of the grape skins the coin was successfully removed by oesophagoscopy.

The frequent impaction of small coins—e.g., farthings—accidentally swallowed, which have a diameter of only 10 mm., shows that it is not always the size of the foreign body that determines its stoppage and lodgment:—

Tilley<sup>33</sup> reports a case where he removed by the oesophagoscope a farthing which had been impacted for five hours in the oesophagus of a boy aged 5 years.

H. J. Davis<sup>35</sup> reports a similar case in a child aged 2 years.

Edward D. Davis<sup>38</sup> mentions a third case in a child aged 19 months, where a farthing was impacted in the oesophagus at the level of the bifurcation of the trachea for one month. The child appeared to be unwell, was wheezy, and frequently vomited. By X rays the coin was localised and by means of the oesophagoscope was easily extracted.

The writer has removed a farthing in a child, aged 2 years, which had been impacted at the level of the second dorsal vertebra for 13 days. (Fig. 34.) Neither liquids nor solids could be swallowed for the first seven days, everything being regurgitated; during the last six days, however, the child was able to swallow milk, and even bread and milk with perfect ease, and there was no regurgitation. Beyond being very fretful and constantly crying, the child appeared to be quite well.

Such cases show that the oesophagus may so adapt itself to foreign bodies that food may pass by without giving rise to any marked trouble.

FIG. 36.—Extraction of coin, first position.

FIG. 37.—Extraction of coin, second position.

Figs. 36 and 37 show the extraction of a coin by the non-slipping forceps with a spatula extremity endoscopic tube.

#### *Tolerance of the Oesophagus to Foreign Bodies.*

That the mucous membrane of the oesophagus is most tolerant to foreign bodies, and especially to pieces of money, is shown by the length of time a foreign body may be impacted without doing any material harm or causing any marked symptoms. Though coins may have been impacted for months and even years with only slight inconvenience, and the disturbance caused by them attributed to other causes, yet, on the other hand, serious complications may occur—i.e., oesophagitis, peri-oesophageal abscess, mediastinitis, ulceration and perforation of the tracheo-oesophageal wall, contractures and strictures (from long-continued presence).

Guisez<sup>39</sup> (Paris) reports the case of a 10-centime coin which he extracted by means of the oesophagoscope, and which had been in the oesophagus for four years. (Fig. 12.)

Balstead<sup>40</sup> mentions the case (previously referred to) of a child aged 5 years, from whom he extracted a 1-cent piece (penny, U.S.A.) which had been impacted in the oesophagus since infancy. It had become absorbed to such an extent that it had lost 25 per cent. in weight, and was not more than two-thirds of its normal thickness. It had lodged in the posterior wall of the cardiac end of the oesophagus and had become embedded or encysted. At the rate of absorption it might have been absorbed in 20 years. In this case but for the X rays the cause of the obstruction could never have been discovered, since the oesophagoscope failed to show it until the wall covering the coin was removed.

FIG. 35.—The author's non-slipping foreign body forceps with revolving shaft allowing the blades to be set at different angles.

Monro<sup>41</sup> reports a case (previously referred to) in which a halfpenny was retained in the oesophagus of a boy for three years.

Kellock<sup>42</sup> has removed a halfpenny with the coin-catcher from the oesophagus of a little girl which had been impacted for three years, and had caused no symptoms.

D. R. Paterson<sup>43</sup> reports a case where a halfpenny had been in the oesophagus for 18 months, and when removed by oesophagoscopy it looked as if it had been dug out of a Roman ruin; yet it had given rise to no ulceration.

Walker Downie<sup>44</sup> had a similar case, where he removed by oesophagoscopy a halfpenny lodged in the oesophagus of a child. When first swallowed the story was not believed, since nothing passed per rectum, and it was not till 18 months later that the case came into his hands, and the X ray was used and located the coin. No permanent injury to the oesophagus was observed.

Singletary<sup>45</sup> has reported the case of a child, aged 2 years and 3 months, who swallowed a 5-cent piece (21 mm. diameter), which became impacted in the lower part of the pharynx and gave rise to two or three attacks of pneumonia yearly for eight years. Finally, a large amount of blood and pus was vomited and the coin passed per anum, eight years and two months after it had been swallowed.

Porter<sup>46</sup> reported the case of a boy, aged 11 years, who had complained of indefinite gastric symptoms for three weeks. He was small for his age, poorly developed and weighed only 2 st. 10 lb. The father stated that the boy had swallowed a halfpenny at the age of 4, and had never been the same since. An X ray showed the coin lying between the fifth and sixth dorsal vertebra. On introducing forceps it slipped away, passed into the stomach, and was evacuated later in the stools. On careful endoscopic inspection no lesion or ulceration of the oesophageal wall could be detected. In two weeks the boy improved so markedly in health that he had put on 5 lb. in weight.

#### *Perforation of the oesophagus and aorta by foreign bodies.*

Are not very rare. Adelman<sup>47</sup> has recorded 14 such cases, Poulet<sup>17</sup>, and Krause<sup>21</sup>. Fatal laceration of the oesophageal walls and perforation, especially of the aorta, has occurred in from a few days to four years. Early perforation, however, according to Poulet, is very rare, only 2 cases having been recorded. Generally the foreign body wounds the oesophagus, or as a result of continued pressure may excite inflammation, followed by ulceration, suppuration, and perforation.

Tilley<sup>48</sup> described a case in which a halfpenny had lodged just below the cricoid region in the gullet for five days. On direct examination the coin was seen lying in an ulcerated area, surrounded by oedematous granulations. It was removed with little difficulty, but the child died the same night from collapse. Post-mortem showed that the oesophagus had ulcerated right through into the trachea, and this had occurred in five days.

Wishart<sup>49</sup> (Toronto) states that a 5-centime piece has caused perforation of the oesophagus within 24 hours.

FIG. 38.—The author's foreign body forceps, showing the blades reversed.

<sup>47</sup> Quoted by H. Chiari, Bert. Klin. Woch., Jan. 5th, 1914.

<sup>48</sup> Proc. Roy. Soc. Med., 1912, vi. (Laryngol. Sect.), p. 42.

<sup>49</sup> Corps Étrangers du Tube Digestif, St. Pierre l'Union Médicale du Canada, December, 1914.

Grey-Turner<sup>50</sup> reports a case where a halfpenny was impacted in the oesophagus of a boy, aged 4 years, for 1 year and 10 months, the boy being able to take his ordinary food and having no difficulty in swallowing. The coin ultimately perforated the aorta and death from hæmorrhage ensued.

E. D. Davis<sup>51</sup> reports the case of a child, aged 2 years, who swallowed a halfpenny. Five years later a little blood was vomited, followed the same night by a profuse hæmorrhage and death occurred. Post mortem it was found that the coin had caused ulceration into the aorta. Also he reports another case<sup>52</sup> where a child, aged 5, swallowed a halfpenny. One week later a radiogram showed the coin in the gullet. It was removed by a skilled oesophagoscopist, but ulceration had already occurred into the left bronchus, and the child died from bronchopneumonia.

Bradley<sup>53</sup> records the case of a man who swallowed a counterfeit half-crown. Eight months afterwards death occurred from sudden

FIG. 39.—Semi-diagrammatic sectional view of the oesophagus, showing the forceps with reversed blade insinuating itself between an oesophageal fold and an impacted coin.

profuse hæmorrhage, and the coin was found to have produced ulceration of the gullet extending into the aorta.

In Jewell's<sup>54</sup> case, already referred to (Figs. 32 and 33), a coin perforated through the oesophageal wall into the posterior mediastinum in 13 days, and caused death. A counterfeit coin<sup>55</sup> has been reported which was impacted for 12 months in the oesophagus of a convict and caused ulceration and perforation of the aorta.

Kellock<sup>56</sup> refers to the case of a lead weight—the diameter of which was just that of a halfpenny—impacted low down in the oesophagus. It ulcerated through and formed an abscess in the mediastinum, eventually causing death in 10 days. He also had a case where a button had been swallowed, and within 10 days it had caused perforation of the aorta.

While it is easy to understand why sharp or angular foreign bodies may give rise to inflammatory and destructive changes in the oesophagus, it is not easy to explain why smooth and circular objects, such as coins, should in some cases cause ulceration and perforation and in others remain harmless and give rise to no symptoms, even though worn and corroded by long sojourn. It is likely that impaction in the neighbourhood of the constrictions, and especially the dangerous regions of the aortic arch, along with excessive spasm of the oesophageal walls, may be the chief predisposing causes. A septic condition of the foreign body and alteration in the secretions may also be a determining factor. D'Este Emery,<sup>57</sup> in discussion, has suggested that the chemical composition of the substance impacted may have something to do with the condition set up, and he considers that whereas copper is a strong antiseptic, as shown by the fact that typhoid cultures placed in a vessel of pure copper become sterile in a few hours, in the case of lead this would not be so. It is interesting to note, however, that metallic poisoning may occur owing to the impaction of copper coins, as shown by the following cases:—

Lee<sup>58</sup> reports the case of a child, aged 5 years, who swallowed a halfpenny. It was forced into the stomach with a bougie. Enteritis followed and death, which was due to the mechanical irritation produced by the passage of the coin through the intestine and to poisoning by the copper, evidence of the existence of the latter in considerable quantities being discovered on testing the mucous membrane and contents of the intestines.

Faucon<sup>59</sup> (Paris) records a similar case.

<sup>59</sup> Bull. de la Soc. de Chir., 1877, iii., p. 158.

### Distensibility of the Infantile Oesophagus.

It is remarkable what large objects may be introduced even into the infantile oesophagus, and the extent to which its walls are distensible, as shown in the cases reported. The oesophagus of a child aged 4 years, which is no wider than 10 or 12 mm. ( $\frac{3}{8}$  to  $\frac{1}{2}$  inch), can be so distended that it is capable of admitting an object of much greater diameter—e.g., a halfpenny, which measures 25 mm. (1 inch)—whilst in addition it will permit the free passage of a metal tube of 10 mm. ( $\frac{3}{8}$  inch) diameter, and even one of 11 or 12 mm. This is not unusual and is possible even with larger coins and at a much earlier age.

In Halstead's<sup>60</sup> case of a child, aged 5 years (already referred to), from whom he extracted a one cent piece measuring 20 mm. in diameter, it was impacted at the cardiac end of the oesophagus. The child had swallowed it during infancy, and was supposed to be suffering from a congenital stenosis which had caused constant regurgitation of food and almost starvation since infancy. The coin was so encysted that it was necessary to corette the posterior oesophageal wall before it was possible to seize the coin with forceps.

McKinney<sup>61</sup> also reports the case of a halfpenny removed from the oesophagus of a child, aged 15 months. It had been firmly impacted just above the suprasternal notch for six days, and only liquids could be swallowed. It required considerable force to dislodge it.

### Rate of Passage of Non-impacted Foreign Bodies.

In those cases where foreign bodies do not become impacted, but safely pass through the food passages, it is interesting to note their rate of passage.

Mosher<sup>62</sup> refers to the case of a baby, aged 1 year, who swallowed a button measuring 25 mm. (1 inch) in diameter. It travelled through the entire alimentary canal, safely negotiated the pylorus, and in 24 hours was evacuated per rectum. It took three days from the time it was swallowed before it was discharged. He also records another case<sup>63</sup> where a mother-of-pearl button, measuring 27 mm., i.e., 1 1/16 inch—diameter, was swallowed by a child 8 years of age, which passed in a few days and gave rise to no symptoms. Also a metal button in a child aged 1 year and 7 months, which remained at the level of the clavicle for three days, was dislodged by the endoscopic tube, delayed at the cardiac orifice of the stomach, and entered the stomach in 24 hours. In 48 hours it had passed the pylorus and was at the brim of the pelvis. Here it was delayed for three days and was then discharged.

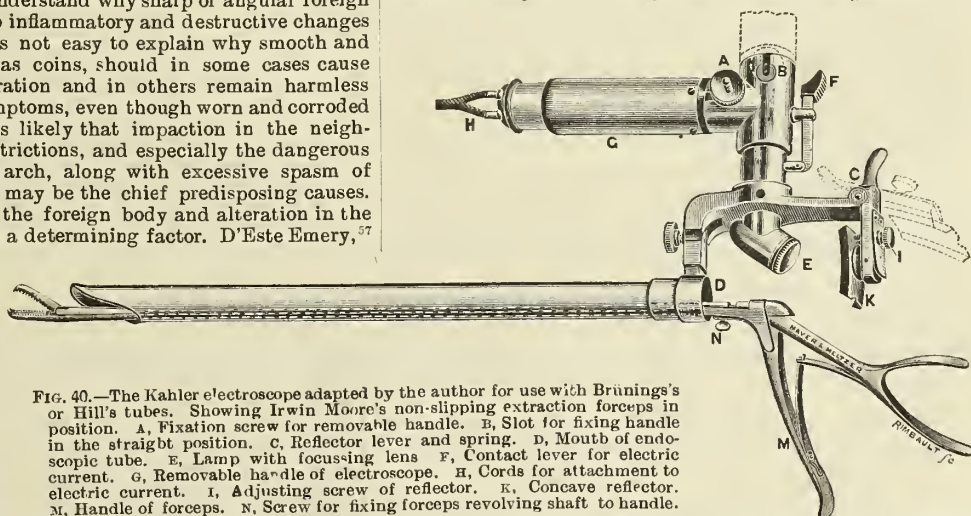

FIG. 40.—The Kahler electroscope adapted by the author for use with Brunings's or Hill's tubes. Showing Irwin Moore's non-slipping extraction forceps in position. A, Fixation screw for removable handle. B, Slot for fixing handle in the straight position. C, Reflector lever and spring. D, Mouth of endoscopic tube. E, Lamp with focusing lens. F, Contact lever for electric current. G, Removable handle of electroscope. H, Cords for attachment to electric current. I, Adjusting screw of reflector. K, Concave reflector. M, Handle of forceps. N, Screw for fixing forceps revolving shaft to handle.

Chevalier Jackson<sup>64</sup> reports the case of a penny located at the level of the cricoid cartilage, dislodged by examination with the examining tube, and passed per rectum in nine days.

It would appear that coins lodge longest of all at the level of the cricoid cartilage, next in the region of the clavicles, and, lastly, at the upper and lower parts of the intestinal canal. They seldom stop at the cardiac orifice, and pass easily and quickly through the pylorus. It is easy to understand why they stick at the back of the cricoid whilst at the sternal level, the thymus gland or arch of the aorta causes constriction of the gullet and may hold them up in this situation.

These cases show the serious dangers of delay, even though in many instances serious symptoms have been long postponed, and that no time should be lost before steps are taken before their removal by endoscopic methods.

## WHEAT CULTURE-MEDIA.

BY SHIOZABURO OTABE, M.D. BÂLE,

MEDICAL SUPERINTENDENT (TEMPORARY), NATIONAL SANATORIUM, BENENDEN, KENT; FORMERLY ASSISTANT MEDICAL OFFICER, KENSINGTON INFIRMARY, LONDON; ASSISTANT, BACTERIOLOGICAL INSTITUTION, TOKIO CHARITY HOSPITAL MEDICAL COLLEGE.

SINCE Pasteur<sup>1</sup> and Koch<sup>2</sup> suggested the use of malt extract for culture-media, many bacteriologists have made a trial of the same, but this has not been successful and malt extract has not come into general use. My own studies of the employment of grain extracts cover a period of nearly 10 years. Wheat is not only much cheaper than meat, but it is more convenient to get and to carry about. It is necessary, too, to keep in mind the sporadic influence of pathogenic bacteria and to prepare both vaccine and immune serum, if possible, at the place where the epidemic broke out and from the actual strain of bacteria which caused the epidemic at that locality. For this purpose the first requisite is to get suitable culture-media. In some places it is difficult to get meat or its extract, though it is easy to preserve them, while wheat can readily be obtained almost everywhere and as readily preserved. My experimental results show that there is no more value in meat-extract culture-media than in wheat-extract culture-media.

*Method of Making Wheat Media.*

1. *Wheat broth*.—A. Roast the wheat (with or without husk) in an iron pan until it becomes brown. B. Put 1 lb. of the roasted wheat without washing into 1600 c.cm. of distilled water. C. Boil this in Koch's boiler for half an hour. D. Strain through a clean cloth. E. Make up to 1000 c.cm. with distilled water if under this quantity. F. Add 0.5 g. of taka-diastase or ordinary diastase and shake the flask well. The temperature of the contents at this time should be maintained at 30° to 40° C. for half an hour. G. Filtration. The resultant fluid ought to be quite transparent with yellowish colour, almost the same as ordinary meat broth. The fluid has a sweet smell, the reaction being slightly alkaline. H. As we make usual broth, add 5 g. of sodium chloride and 10 g. of peptone albumin, then boil and filter.

2. *Wheat agar*.—Add 15 g. (in winter) or 20 g. (in summer) of agar to the above quantity. For the rest the preparation is almost the same as that of meat agar as usually prepared. Many special culture-media can be made of the wheat broth and agar media.

*Cultural and Agglutination Tests.*

To compare the rate of bacterial growth on the various media I used *Staphylococci albus* and *aureus*, *B. coli*, *B. typhosus*, *B. dysenteriae*, *Vibr. cholerae*, and others, and found almost the same growth in each case on the different media.

The difference of agglutination reaction of the bacteria cultivated on two different culture media was then tested.

*Staphylococcus.**B. coli.*

Dilution of serum.	Cultured on—		Dilution of serum.	Cultured on—	
	Wheat agar.	Meat agar.		Wheat agar.	Meat agar.
10	+	+	25	+	+
50	+	+	50	+	+
100	+	+	10	+	+
200	+	+	200	+	+
300	—	—	400	+	+
			600	—	—

Agglutination positive, +; negative, —.

For therapeutic purposes I have made autogenous vaccines from cultures of the above-mentioned bacteria on wheat media and observed good results.

*Summary.*

The experimental results given prove that wheat can be used instead of meat for culture media. As the wheat-

Growth of *B. coli* on wheat culture media and ordinary meat media compared. A, Wheat broth; B, Ordinary broth; C, Ordinary agar; D, Wheat agar.

extract culture-media contains maltose, they can be used as special media for particular bacteria and for diagnostic purposes.

## Reviews and Notices of Books.

*Trench Fever: a Louse-borne Disease.* By W. BYAM, J. H. CARROLL, J. H. CHURCHILL, LYN DIMOND, V. E. SORAPURE, R. M. WILSON, and LL. LLOYD. With an Introduction by Sir T. H. GOODWIN, K.C.B., a Foreword by Sir DAVID BRUCE, and a Summary of the Report of the American Trench Fever Commission by R. H. VERCOE. London: Henry Frowde and Hodder and Stoughton. 1919. Pp. 196. 10s. 6d.

THE findings of the War Office Trench Fever Investigation Committee have now been made available in an attractive volume of the Oxford Medical Publications. The committee, under the chairmanship of Sir David Bruce, was composed of the following workers: Lieutenant-Colonel D. Harvey, Mr. A. W. Bacot, Major W. Byam, Lieutenant-Colonel H. French, Mr. J. A. Arkwright, Sir W. M. Fletcher, Lieutenant A. F. Hird, and the late Professor H. Plimmer; their results are adequate testimony to the great possibilities of well-coordinated research work. It is certainly true that much remains to be found out about trench fever. We are still completely ignorant of the causal organism, as of any efficient means of treatment, but the positive incrimination of the louse as the carrier of the disease points us well on the road.

It has been argued that trench fever is a war disease and will perish unaided when the trenches are filled in. Sir Charles Burtchall, in a recent address dealing with disease as affecting success in war, said: "With the cessation of hostilities the disease [trench fever], for the moment at all events, ceased to be of any immediate practical importance, as it was only under the conditions of trench life that there were real difficulties in keeping troops free from lice." The authors do not agree with this view. There is evidence, they say, that the disease has existed since the twelfth century, and certainly so long as lice are allowed to dwell in security among men there will always be the danger of its reappearance. Neither can we afford to overlook the possibility of the human race being again confronted with the horrors of warfare, minor as well as major.

In a foreword written in May, 1918, Sir David Bruce reviews the research work carried out in England, France,

<sup>1</sup> Études sur la bière, Paris.

<sup>2</sup> Mitth. a. d. K. Gsndhtamte., i., I., Berlin.

and Germany up to that date, and shows that no satisfactory evidence on the transmission of the disease had been brought forward when the British and American commissions began their task at the end of 1917. He pays a warm tribute to the courage of those who volunteered as experimental subjects, and without whose self-sacrifice no progress could have been made. The account of these experiments in the chapter on transmission makes romantic reading. By means of the very exact work done in the laboratory at Hampstead several conclusions of vital importance to prophylaxis were finally arrived at. Trench fever is not a disease caused by normal lice, but the excreta from pediculi fed on trench-fever patients, applied to an abraded skin area, are capable of producing a febrile illness similar in its relapsing character and general clinical picture to the disease at present known as trench fever. Louse excreta may be virulent without the presence of vermin, and this virulence is retained in the excreta even after so long a period as 120 days. The infection is not communicable by the mouth, but it has taken place through the unbroken conjunctiva. The excreta can infect when introduced subcutaneously, and although the causative organism has not been isolated the outline of its life-history is beginning to take shape. When lice are fed on patients during an afebrile stage of the disease they become capable of conveying the infection. This infection is therefore present in the peripheral blood of the human subject during the afebrile intervals. It is also claimed that the number of trench fever organisms passed by the lice increases as the time from the infecting blood-feed lengthens. The incubation period in the human subject was never less than seven days, but varied up to 16 days as the infecting dose was decreased.

The chronic disease is carefully described, particular attention being devoted to the vagal disturbances of the circulation. There is a short chapter on prognosis which should be useful to members of pensions boards. The main suggestions in regard to treatment are concerned with prophylaxis, and as the most important measure of prophylaxis is the extermination of lice this chapter has a wider application than any other part of the book. It will, for example, be read with interest by those who are at present engaged in suppressing typhus in Central Europe.

The report of the Commission of the American Red Cross Research Committee on Trench Fever—a review of which appeared in THE LANCET of Oct. 12th last year—is summarised by Lieutenant R. H. Vercoe in the concluding appendix. That the louse is the main ætiological factor in trench fever is common to the conclusions of both British and American Commissions, but whereas the British regard the louse-bite as an uncommon mode of infection, this is looked upon as the most frequent origin of the disease by the American Commissioners. The agreement is, however, more important to preventive medicine than the difference. The publication of this work should stimulate thought and lead to further important discoveries.

*Massage and the Original Swedish Movements.* By the late KURRE W. OSTROM. Edited by P. SILFVERBERG, G.D. Eighth edition, illustrated. London: H. K. Lewis and Co., Ltd. 1919. Pp. x.-196. 5s. net.

THE author admits that "several movements belonging to the Swedish system have been omitted," and so the reader of this little book will not expect to find in its pages all that is to be known of Swedish massage and movements. It is, in fact, a compendium of elementary lectures. The fundamental positions and Swedish exercises described are clearly expressed and well illustrated. But in other respects the medical man will find much to criticise. For example, almost equal space is devoted to what can only be described as "beauty massage" and to the treatment of all types of recent injury, while the elementary doctrine of inhibiting the action of antagonistic muscles when treating a case of paralysis is referred to as a "recent experiment." The best section is that which deals, very shortly, with spinal curvature, but differentiation is lacking between cases of advanced scoliosis and static or postural curvatures. A short chapter on massage treatment in America leads the reader to the conclusion that the sooner some recognised standard of training is established the better it will be for the general public. The bibliography is unusually full and satisfactory.

*Essentials of Surgery.* By ARCHIBALD L. McDONALD, M.D., The Johns Hopkins University, Lecturer on Surgery, Nurses' Training School, St. Luke's Hospital, Duluth, Minnesota. With 46 illustrations. London and Philadelphia: J. B. Lippincott Company. 1919. Pp. 265. 8s. 6d. net.

THIS volume is an addition to the Lippincott Nursing Manuals. It is designed for the use of senior nurses and is written in the belief that a nurse can assist in the care of her patient more intelligently if she be primarily equipped with a reasonable knowledge of the injuries and diseases with which she is likely to meet. The notes make no attempt to discuss technical nursing details or to provide an elaborate treatise on anatomy, physiology, or bacteriology. The advantage of this is seen in the fact that in so small a volume the author is able to deal adequately with the essentials of surgical disease.

The diagrams are very simple and clear, the subject matter is laid out well, according to systems. At the end of each chapter is a list of demonstrations suitable for illustration of the various points detailed therein which will be of great practical value to those who lecture to nurses. A brief but useful glossary of medical terms is to be found at the end of the volume.

To compile a book of this nature requires knowledge of nurses as well as nursing. It is, moreover, a matter of difficulty to strike the happy medium between a treatise on surgery and a guide-book to the intelligent nursing and treatment of disease. In our opinion the author has succeeded in both these respects. The nurse who is really keen will be able to satisfy her thirst for knowledge of surgery in this book alone; while to the surgeon who is called on to give lectures to nurses this book will be invaluable for both junior and senior courses.

*A Manual of Gynecology.* By JOHN COOKE HIRST, M.D., Associate in Obstetrics, University of Pennsylvania. With 175 illustrations. London and Philadelphia: W. B. Saunders Company, Ltd. 1918. Pp. 466. 12s.

IN this little manual the author has presented the arrangement of the subject he has used for the last 20 years in his teaching. The book contains a considerable amount of information in a concise and clear form. We may not agree with all the author's teaching or methods of treatment, but the work is a good example of its kind and should prove helpful to the students for whom it has been written. Whether it is wise, or, indeed, necessary, to increase the size of such a book by including chapters on diseases of the breast, the urinary tract, and the rectum is a matter upon which there may well be some difference of opinion; we do not think it is. The illustrations are fair, and the index is a good one.

*The Exact Diagnosis of Latent Cancer.* By O. C. GRUNER, M.D. London: H. K. Lewis and Co., Ltd. 1919. Pp. 79. 7s. 6d.

THIS book is essentially one for the clinician and clinical pathologist, but in many places the meaning is obscure from the arbitrary use of newly-coined technical terms. Although it would be impossible without voluminous quotations to give a summary of Dr. O. C. Gruner's book, we must remark that statements such as "lymphocytosis indicates relative alkalinity, lymphopenia relative acidity, of the serum," are freely introduced without evidence to support them. The author is an enthusiast, but, we fear, has little prospect of becoming a pioneer until he enshrines his views in less cumbersome language, and is more detailed in his evidence.

**FREEMASONS' HOSPITAL FOR PAYING PATIENTS.**—Under the presidency of the Lord Mayor a meeting was held at the London Mansion House on Sept. 19th to discuss a scheme for the utilisation of the Freemasons' War Hospital (formerly the Chelsea Hospital for Women) as a nursing home for paying patients of limited means who are members of their craft and their families. It was decided to submit the matter to a meeting of representatives of the lodges which had taken part in the founding of the war hospital, and other supporters, to be held at the Mansion House on Oct. 10th, at 4 P.M.

# FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of

Professor CHARLES ACHARD,

AND

Dr. CHARLES FLANDIN, D.S.O.,

PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE  
UNIVERSITY OF PARIS.

CHEF DE CLINIQUE A LA FACULTÉ DE PARIS.

## DYSIDROSIS: ITS PARASITIC NATURE.

By J. DARIER,

PHYSICIAN AT THE HOSPITAL OF ST. LOUIS; MEMBER OF THE  
ACADEMY OF MEDICINE.

DURING the war I have noticed that whenever a soldier, either from the armies or the interior, presented himself at a dermatological consultation for a vesiculo-bullous or squamous eruption limited to the hands and feet, three diagnoses were usually considered: eczema, occupational dermatitis, or dysidrosis; very exceptionally a parasitic mycotic affection was thought of.

It is necessary, first of all, to examine what these diagnoses mean. What is understood by *eczema*? Standing by itself, this term entirely lacks precision. Do we mean *true* or *diathetic eczema*, which I have suggested calling *eczematosis*? It would then be a matter of a disturbance of metabolism, thanks to which the skin possesses an exaggerated vulnerability and reacts in *eczematous* form to the slightest and most various irritants. It must be remarked that this morbid state is hardly ever found in the case of adults enjoying good general health, and that there is no reason for the eruption to be confined to the extremities.

Have we got *seborrhoeic eczema* in our mind? It prefers to localise itself on the head and trunk, and only reaches the palmar and plantar regions exceptionally, never exclusively. On the other hand, the professional *eczemas*, whether caused by medicaments or otherwise, grouped under the name of *artificial dermatites*, have their seat in the hands, and are far rarer on the feet. It is well known that the particularly exposed professions are those of mechanic, factory, and laundry hands, scullions, masons, painters, photographers, hairdressers, grocers, and gardeners; that these artificial dermatites can be provoked by a crowd of irritant substances, such as the various forms of mercury, phenol, antiseptics generally, reducing agents, distilled oils, &c. The initial topography of the lesions and inquiry about the occupation of the patient very quickly make it clear whether one can stop at this interpretation. Very rarely one will have to deal with intentionally provoked dermatitis, the origin of which is concealed by the patient. As for *Tilbury Fox's dysidrosis*, *Hutchinson's chiropompholyx*, or simply *pompholyx*, it is a vesiculo-bullous dermatitis, later on squamous in type, which has as essential character its limitation to the hands and feet. According to the authors, the eruption comes on in recurring attacks, especially in spring and summer. It appears symmetrically on both hands or both feet, or on all four extremities at once; it announces itself by a feeling of "burning or tingling." It often comes on after profuse perspirations, violent exercise, or a nervous shock, in both sexes and in adolescents and adults. The authors very generally make it appear that dysidrosis patients are almost always overworked, dyspeptic, neurasthenic, nervously depressed people. According to these data dysidrosis would be a particular kind of eczema arising from sudation or a hyperidrosis in subjects predisposed to it by their general state.

## Characteristics of Eczema and Differential Diagnosis.

The following characteristics are specially given as distinctive marks of "*eczema*": the topography of the eruption; the deep seat of the vesicles, which, especially on the lateral faces of the fingers, resemble "boiled sago grains embedded in the skin"; the fact that the vesicles, and the blisters resulting from their coalescence on an only slightly inflamed basis, have little tendency to burst, do not run plentifully when opened, but on the contrary dry up within 10 or 15 days, leaving circles or polycyclic surfaces edged with an epidermic collar. The relation which T. Fox believed to exist between the vesicles and the sudoriparous canals has been shown to be only accidental by Hutchinson, Robinson, R. Crocker, W. Williams, and myself. In none of the publications with which I am acquainted is any mention made of the state of the nails, which I have always found intact in cases labelled dysidrosis.

Within the last 15 years it has been found that various *epidermomycoses* can more or less exactly imitate dysidrosis and the *eczemas* of the extremities. There is firstly *palmar and plantar trichophytosis*, which Djelaleddin Mouktar was the first to describe clearly to the French Society for Dermatology and in the *Annales de Dermatologie* in 1892, based on the cases which he had observed when working under our master, Professor A. Fournier. As marks distinguishing it from dysidrosis he indicates the following: habitual unilateralness, vesicles less numerous and less scattered, less pruritus; in the period of desquamation extensive erythematous-squamous blotches clearly circumscribed, edged with a very clean epidermic collar, with frequent reproduction of some vesicles within the area of the blotches or on their circumference. Finally, and above all, microscopic examination of the roof of the vesicle and the squamous cells reveals the presence of a spore-like mycelium, sometimes very abundant, sometimes hard to discover. In short, this palmar and plantar trichophytosis presents itself in a very special aspect; it ordinarily resembles psoriasis or the syphilides usually found in those regions rather than dysidrosis. Then there is *epidermophytosis*, with which the works of Sabouraud from 1907 to 1910 have made us acquainted. This mycosis is due to a parasite nearly allied to the trichophyton, the *Epidermophyton inguinale* *sensu intertriginis*, which does not attack the hairs. *Epidermophytosis* has two favourite seats. In the groin and at the top of the thigh it causes the eruption known as *Hebra's eczema marginatum*; there are bright rosy, round or polycyclic patches, extending rapidly, with clear edges, scalloped and often delicately vesicular. This *eczema marginatum* may invade the abdomen, the arm-pits and other parts of the trunk, but this is not common. The other very common habitat of the *epidermophyton* is the interdigital space between the toes. It produces what is known as *intertrigo of the toes* or *intertriginous eczema of the toes*, and betrays itself by a macerated epidermis, covering a red base and sometimes raised by vesicles and blisters. In his article in the *Annales de Dermatologie*, June, 1910, Sabouraud points out that, starting from this centre, the lesions may reach the instep in *eczematous* form, but according to him they would not invade the smooth epidermis of the fore part of the foot; they are endless in duration. He believes *epidermophytosis* to be much rarer on the hands; it betrays itself on the lateral faces of the fingers by irregular vesicles, scattered, disorderly, without forming any trace of a circle; their appearance is so exactly like eczema, and in some cases like dysidrosis, that the differential diagnosis with eczema and dysidrosis can only be established by microscopical examination. This reveals in the squamæ and in the roof

## PHOTOGRAPHS ILLUSTRATING TRICHOPHYTOSIS AND DYSIDROSIS OF DIFFERENT TYPES.

FIG. 1.—Palmar trichophytosis.

FIG. 2.—Parasitic dysidrosis of the sole of the foot, vesiculo-bullous type.

FIG. 3.—Parasitic dysidrosis of the hand, squamous type.

FIG. 4.—Mycellum of the trichophyton in the squamous cells of the epidermis.

of the vesicles delicate filaments of mycelium, slightly *cloisonné*, or on the contrary divided into short, almost cubical elements, sometimes very numerous, sometimes rare and hard to find. In short, the lesions of epidermophytosis of the extremities bear slight resemblance to those of trichophytosis, but great resemblance to those of eczema and dysidrosis.

During the war the ætiological conditions to which dysidrosis is attributed have been realised on a large scale. A huge number, young and adult, of all temperaments, from all classes of society, have been subjected year in year out to repeated exertions, with profuse sudations, and in a word to prolonged overwork; moreover, the causes of dyspepsia have not been wanting, any more than occasions of nervous shock or depression of spirits. In such circumstances one might expect to meet with numerous cases of dysidrosis, especially in certain groups which have been particularly overworked. Now this has not been the case.

#### *Experimental Investigation of Typical Skin Lesions.*

Amongst soldiers attacked by vesiculo-bullous or squamous eruptions on hands or feet I have found: 1. A huge majority of secondary eczema due to scabies, sometimes to pediculosis, often to boils, ecthyma, impetigo, and suppurating wounds. 2. A fairly high number of *professional dermatitis* explained by the occupations of the patients. 3. Some exceptional cases of *palmar trichophytosis*, an example of which I reproduce here (Fig. 1), verified by microscopic examination and culture, in which I was never able to find out the origin of the contagion. 4. Finally, a respectable number of cases of eruption reproducing the picture of dysidrosis. When I observed them these cases affected one of the following types:—

(a) *Vesicular and bullate type*.—On the hands there were generally delicate, clear vesicles scattered or vaguely grouped on the palmar and lateral faces of the fingers, on the palm, and sometimes also on the back of the hand; lenticular or bullous vesicles, often with puriform contents, occupying the fore part or the whole sole of the foot, as in the case depicted here (Fig. 2). Sometimes blisters may have been burst on the march, and I have seen some of them become the origin of lymphangitis.

(b) *Vesiculo-squamous type*.—The lesions consist of erythematous-squamous blotches, multiple and scattered, or confluent into sheets, circinate in certain places only, and usually with crumbling edges; these blotches are sprinkled and surrounded with a few vesicles or small brownish crusts resulting from the drying up of the vesicles.

(c) *Squamous type*.—There are dry circumscribed desquamations, delicately lamellar or thicker, disclosing rosy and smooth or squamous epidermic surfaces; it is an exception when their shape is circinate or polycyclic, being usually irregular, with wavy edges, which recalls that of eczema rather than that of a parasitic affection. (Fig. 3.) On the feet erythematous-squamous blotches fill the fore part of the foot, often the back of the toes and the neighbouring region, as also the plantar arch, more rarely the heel. They constantly coincide with intertrigo of the toes.

The three types, which I mention here separately in order to emphasise the various aspects which I have met with, are evidently only stages in the evolution of the same eruption, but these stages can coexist at various points of the same extremity. Further, it seemed to me certain that every desquamation does not necessarily follow on a visible vesicular process, and that the affection can persist and progress in the form of dry desquamation. Is this dermatosis really T. Fox's dysidrosis, Hutchinson's pompholyx? Is there not amongst these dysidrosiform or eczematoid eruptions a certain number of cases of epidermic mycoses, and especially of epidermophytosis? In order to find out I have submitted the roofs of the vesicles or the squamæ of these dysidrosiform eruptions on hands and feet to microscopic examination as often as possible. Besides negative cases I have found positive ones, exactly identical with the others, in which I have found, either easily or sometimes with great difficulty, a mycelium analogous to that on Fig. 4.

All the examinations were made by me or under my control in my own laboratory.<sup>1</sup> When the first attempt

proved negative we adopted the following method: The shreds of epidermis were fixed and the fat removed in alcohol-ether, then separated with needles in acetic acid, finally cleared on the slide in 40 per cent. caustic potash with gentle heat. It was sometimes necessary for success to make several examinations at an interval of some days and to spend several hours in examining the preparations. I have kept a record of the cases from February onwards. My return refers to 20 patients, three-quarters of whom presented themselves during June, July, and August. In 5 of them all four extremities were affected, 9 had dysidrosiform lesions of the hands, and 6 dysidrosiform lesions of the feet. The total positive results were 11 to 14 for hands and 6 to 11 for feet. I must draw attention to the fact that negative results became more and more rare in proportion as we employed improved technique and greater patience in our investigations; in fact, since September we have only had positive cases, one of which required altogether four hours of work. If I were asked what my general impression is, I should say that I believe to-day that T. Fox's dysidrosis does not exist as a distinct cutaneous disease with a nosological individuality; that the clinical picture portrayed with great perfection by Fox and Hutchinson corresponds to a parasitic dermatosis—epidermophytosis of the extremities. It will be necessary, however, for further investigations to confirm or upset this conclusion, which I fully acknowledge at present goes beyond the range of the facts observed by me. It will also be necessary to make sure by cultural methods which is the parasite in question and whether it always belongs to one and the same species or not. The morphological aspect of the mycelium in the squamæ does not allow of settling the question; this is true of the one depicted in Fig. 4, which is taken from my "Précis de Dermatologie." Sabouraud himself, whom I consulted on this point, told me that he could not say whether it is the mycelium of an epidermophyton that is in question or some species of trichophyton, which alone would certainly be the case if we are in presence of a mycosis of the epidermis.

#### *Mycotic Nature of so-called Dysidroses.*

I should like to close by pointing out how the hypothesis set up by me as to the probably constantly mycotic nature of the so-called dysidroses fits in with the clinical facts and, on the other hand, with the classic data of dysidrosis and epidermophytosis. It is said that attacks of dysidrosis usually last for from 10 to 20 days and often recur in the same subject. This is true of epidermophytosis of the extremities, but it must be added that one also sees continuous or subintraut attacks prolonged for six months or more. I have met soldiers who have been made useless for more than half the war by parasitic dysidrosis. Of the ætiological conditions to which dysidrosis is attributed, those which relate to the nervous state, overwork, or dyspepsia are too banal to be considered. The influence of the seasons and the effect of profuse perspiration might consist in the fact that they favour parasitic vegetation. As for the topographical distribution of the lesions, epidermophytosis, like dysidrosis, attacks hands, feet, or all four extremities symmetrically at the same time. Epidermophytosis has in addition a favourite seat in the interdigital spaces of the toes, where it is very common; it may persist there for very many years, causing only slight annoyance or even without the patient being at all aware of its existence; thence it proceeds to invade the rest of the feet and doubtless the hands also by auto-contagion, thus producing dysidrosiform attacks under the influence of occasional causes. The inguinal site of epidermophytosis, where it betrays itself by Hebra's eczema marginatum, is perhaps nourished from the same source; but the fact that this eczema marginatum often occurs in the form of small epidemics in boarding-schools, asylums, agglomerations of young people, seems to indicate that it is due rather to hetero-contagion by the linen or the water-closets. But it must be remarked that if the coexistence of eczema marginatum in the groin with parasitic dysidrosis on the hands and feet is not very common, its coexistence with parasitic intertrigo of the toes is, as a rule, nearly general.

Lesions of the nails have not been noticed in dysidrosis, nor have I observed them either in epidermophytosis of the hands and feet, save as chance coincidence. But, on the contrary, it is noticed that the nails are very commonly affected in eczemas and professional dermatitis of the

<sup>1</sup> I desire to thank Miss Eliacheff, my assistant, whose experience and devotion have been invaluable to me in these investigations.

extremities. It follows that the good or bad state of the nails can, in my view, serve as a retrospective diagnosis of a dysidrosiform attack which would be healed at the time of seeing the patient.

As for the treatment of dysidrosis internal medication is advised, using tonics, and especially arsenic, which can obviously only be intended to improve the general state; soothing dressings and refreshing or slightly disinfectant ointments are recommended. Epidermophytosis, on the contrary, demands repeated rubbing for several weeks with iodised alcohol (from 1 in 60 to 1 in 30) or strong chrysarobin ointment (from 1 in 300 to 1 in 100), together with persistent removal of the desquamating epidermis. I have been able to assure myself that the treatment with iodised alcohol has relieved, and even cured, cases of dysidrosiform eruption in which we have not found the mycelium, probably for lack of enough perseverance in our microscopical investigations.

#### Conclusion.

T. Fox's dysidrosis or Hutchinson's pompholyx is not a distinct illness; what has been called by that name is only a clinical picture, a symptom-complex which may be called *dysidrosiform*. When they are not artificial, professional, or medicamentous dermatitis, the dysidrosiform eruptions are mostly, and probably always, of mycotic nature, and due to the epidermophyton; careful and sometimes very laborious microscopical examination will provide the proof; they must be treated as such. If we want to retain the term dysidrosis it must not be considered as giving a precise diagnosis, but must be completed by some qualifying term, as done, for example, with the term sycosis. Therefore, when one is faced with a dysidrosiform eruption, the problem is to decide between the following two diagnoses: (1) parasitic epidermophytotic dysidrosis; (2) non-parasitic dysidrosis or occupational dysidrosiform dermatitis.

## THE CONTAGIOUSNESS OF FAVUS IN MAN.

BY R. SABOURAUD.

MOST doctors and all dermatologists are acquainted with the name and symptoms of tinea favosa, its persistence, the characteristics of its straw-coloured crusts, forming a rocky protuberance on the scalp and in consistence, appearance, and method of crumbling away suggesting baked earth or dry clay.

I am not going to dwell on the clinical description of this malady, as I should like to consider it from another point of view. The problem of the contagiousness of human favus and its prophylaxis has presented itself in a specially urgent way during the war on account of the utilisation of African colonial troops, amongst whom favus is of frequent occurrence. It is therefore not without interest to face this question as it actually presents itself, not according to theories or preconceived ideas, but according to the facts.

Nowadays, when the parasite causing the disease is known by all, one is always inclined to conclude that because it is parasitic this disease is very contagious. But one must not *pre-judge* a question, one must *judge* it. History tells us that the contagious character was just as much in doubt before as after the discovery of the parasite.

In general—in our country and colonies and adjacent territories, at least—what one sees are sporadic cases scattered amongst an immune population, amongst which there have always been a few cases. And if we call to mind the ætiological conditions in the midst of which the cases arise, it is poverty, filth, promiscuousness, and destitution which seem to constitute the usual environment necessary to bring them about.

When one examines an accumulation of crusts, or pits, of favus, and sees under the microscope the enormous felted mycelium which forms them, when one thinks what an amount of seed such crusts could produce to create new cases, the conclusion is inevitable that favus is very slightly and very rarely contagious, and that it calls for very special

and very rare circumstances for it to be able to implant itself in the human skin. In the midst of a rural, pastoral, poor population, where no ideas of hygiene exist, and where the human being lives very much in the same way as his domestic animals, 10 or 15 cases may be seen, and the number hardly increases. These cases are scattered. If a single family will sometimes produce two or three, there will usually be also healthy children in the very same family who will escape contagion. Most frequently some direct ancestor, father, mother, or grandfather, will be found who has been affected with favus for 30 or 50 years, and has been the origin of the contagion. In this way small centres exist from generation to generation, and no doubt one might find families in which favus has continued for several centuries without having brought any real epidemic. This means that, when not treated, favus is of illimitable duration. The favus patient who is not treated for the disease will die a favus patient; and in the course of an illness of 30 years or more the patient will have created one or two new cases. But these are just the conditions which favour the endemicity and perpetuity of the malady. Each case lasts indefinitely, and produces one or two others in its neighbourhood. Going back a century one would find practically the same picture in the same families. In this connexion nothing is more instructive than Ciarrochi's most circumstantial work on favus in the Transiberian region.<sup>1</sup> On turning over the pages of the register of the hospital of San Gallicano he was able to ascertain that 5374 cases of favus were treated there during the whole of the nineteenth century, all these cases coming from the province of Rome, and nine-tenths of them from the south-eastern part of the province situated below the Tiber. Nearly all of them came from rural districts. Two-thirds of the patients were boys, one-third girls. The age of contagion, the second stage of infancy; extreme cases from 2 to 18 years. In this way Ciarrochi has traced families which have been producing cases of favus for three generations. And this country which has given birth to 5374 cases of favus—evidently an incomplete return—had at the end of the century just about as many as at its beginning. Extend Ciarrochi's survey and you will have the normal story of favus all over the world. It is always the same whenever observations are made.

#### Rare Occurrence of Contagious Type.

But can we say "always"? To speak the truth, no, not always; and I must describe the very rare occasions when I have been able to see favus of a contagious, and even very contagious and epidemic type. And as on all three occasions the story has been identically the same, it is probable that it will be found in a similar form again. But it must be emphasised that the facts have been seen only three times in 30 years of close and daily observation. They are therefore exceedingly rare. Even if he gives special attention to these questions, a specialist might never have met with similar cases. They are so rare that some experienced dermatologists who have not witnessed such facts will be inclined to doubt them. But I can guarantee their absolute correctness. A 6 to 12 years old child is brought to the doctor for a crust adhering to the middle of the scalp and refusing to disappear. This crust, grey, flat, as thin as the nail, without relief, very adherent, cannot be moved to and fro on the skin. If you make a fold in the skin the crust breaks and a little serous fluid exudes through the cracks. The colour of this crust is an ash-grey, recalling the colour of wasps' nests in the woods. It is from  $\frac{1}{2}$  to 1 mm. thick. If it is removed with the curette, it leaves beneath it the red, moist, bleeding skin, similar to what is found beneath the old conglomerated cups of favus. Examination of this crust in small portions under the microscope shows that it is formed exclusively of felted mycelium like the cup. Culture gives the common Schönlein's *Achorion*, without any peculiarity to explain the strange behaviour of this clinical form, for its behaviour does indeed differ widely from ordinary favus. This crust, which is 2, 3, or even 5 cm. across at its greatest diameter, is formed in a few weeks and increases visibly from day to day. When you meet with this clinical type you may rest assured that in the school to which the

<sup>1</sup> G. Ciarrochi: La répartition géographique du favus dans la province de Rome. C. R. du IV<sup>ème</sup> Congrès international de dermatologie, Paris, 1900, p. 439.

child goes you will see five, six, ten cases of contagion arise, ten cases which will develop with the same rapidity. If the disease is allowed to extend, the crust will thicken at isolated points which will be milium cups, and later on there will be a rock of crusts. It is therefore a squamous favus at the outset. If favus always behaved like that it would be the most formidable of tinea. Nothing could be more contagious. But these cases are so exceptional and abnormal that if I had not seen them with my own eyes I should be tempted to charge this description with being exaggerated.

Under certain undetermined conditions, then, common favus may give place to this *papyroid* type, very contagious amongst children and extending rapidly. And as one, so to say, never sees favus at its very beginning, it might be that it begins in this way more often than one thinks and that an old case of favus can pass through a period of reproduction after a long period of apparent stagnation. But that is only a hypothesis. We know nothing of the precise conditions which govern the cases of which I have just been speaking, any more than of the conditions which cause the habitual inertia of the others. In any case it must be clearly noted that these facts have never been observed except in children, and that this form of favus seems, like all favus, to be contagious only in the case of children.

The rare cases in which one can surprise favus at its beginning are mostly cases of favus on the body with circles recalling ringworm, on the circumference of which little golden-yellow cups are scattered. But nearly always in such cases an animal favus of a special species is concerned. Now, nobody has ever seen a single case of favus of the scalp caused in human beings by any other achorion than Schönlein's achorion, human species. Consequently these accidental inoculations of favus from animals to man, which may be observed even in adults, are of little practical importance.

#### *Importance of Age and Hygienic Conditions in Favus Contagion.*

I must again insist on the importance of age in favus contagion. Since we have to deal with a disease of indefinite duration and we find it in adults or even old men, we might think that every individual at every age can contract favus. That is a mistake. Ask all the patients you meet and they will all tell you that they contracted favus at school age. From this special point of view of the age of contagion, favus belongs therefore to that class of tinea the inoculations of which into the scalp are not found after puberty. Doubtless animal favuses are an exception, such as the animal trichophytoses, but they are found only on the body, where they are easily curable. When, therefore, it is considered necessary to isolate soldiers attacked with favus, for fear that they might infect their comrades, it seems to be a precaution which may appear a luxury in time of war. It would be more logical to cure them after the war, before they return home, rather than to deprive the army of men who are otherwise normal, for they will not spread contagion amongst their adult comrades. I am not aware of a single exception to this rule having been observed amongst all our North African troops, or of a single case of the transmission of favus having been discovered in adults.

Another general remark, not without importance, results from observation of our North African Colonial troops. In those regions tinea are hardly found except amongst the poor and subject populations, both Arab and Jewish; they are not found amongst white colonists, not by reason of any immunity, but on account of the different hygienic conditions. In Fez and South Morocco tinea are innumerable and favus very common. For until we occupied the country they were considered incurable and were not treated at all. The number is now decreasing daily. Favus is, therefore, more than other tinea, a morbid type which civilisation ought to remove gradually. Our municipal dispensary in Fez, installed by my collaborator and friend, Dr. Noire, is a model from this point of view. Three radiotherapeutic apparatus are permanently at work, and the natives now present themselves for treatment of their own accord. If this practice is continued there will not be a single case of tinea in all the region a few years hence.

It is not intended in this place to study the treatment of favus, but this much may be recalled. The treatment,

briefly, involves local prophylaxis in the shape of scraping with the enrette and 1 per cent. iodine in alcohol. Superficial cleansing having been thus performed, one passes on to curative treatment by means of X rays and 1 per cent. chrysophanic ointment, when it can be borne without irritation. It must not be forgotten that in favus, when the hair grows again after application of X rays, some hairs still remain affected with the parasite, so that complementary epilation in detail is necessary. This can be performed with tweezers, for the eye of a skilled worker can distinguish the doubtful hairs (centring in a red point) amongst the healthy growth. But I will not pursue the matter further, for this is not a therapeutic article but a simple note laying down the conditions ordinarily governing the transmission of favus and the considerations which must guide its prophylaxis.

The French Supplement to THE LANCET—under the Editorial Direction of Professor Charles Achard, Professor of Pathology and Therapeutics in the University of Paris; and Dr. Charles Flandin, D.S.O., Médecin-Major de 2me Classe, Chef de Clinique à la Faculté de Paris—has appeared on the dates given in the following list, which sets out the titles and authors of the contributions:—

Sept. 21st, 1918: (1) The Microbic Diversity of the Enteric Fevers, by Professor Achard. (2) Post-Typhoid Atony of the Cæcum, by Maurice Loeper, Professor of the Faculty of Medicine and Physician to the Paris Hospitals.

Oct. 19th, 1918: (1) What the War has Taught Us about Tetanus, by Louis Bazy. (2) Tetanus Consecutive to Superficial Wounds and to Trench Foot: Treatment and Prevention, by Professor Raymond, Médecin Principal de 2me Classe.

Nov. 30th, 1918: (1) General Review of French Cardio-Pathology during the War, by Ch. Lanby, Physician to the Paris Hospitals, Médecin Major de 2me Classe. (2) Methods of Estimating Augmentation in Depth of Volume of Left Ventricle, by Dr. Bordet, Director of the Radiological Laboratory of the Centre of Cardiology of Professor Vaquez, Hôpital St. Antoine.

Jan. 11th, 1919: (1) Gunshot Concussion of the Spinal Cord, by Henri Claude, Professor in the Paris Faculty of Medicine, Physician to the Paris Hospitals; and Jean Lhermitte, formerly Chef de Clinique in the Paris Faculty of Medicine. (2) Contribution to the Study of the Manifestations of Emotional Shock on the Battlefield, by Cl. Vincent, Physician to the Paris Hospitals, formerly Medical Officer to the 46th and 98th R.I. and to the 44th B.C.P.

March 1st, 1919: The Surgical Complications following Exanthematic Typhus, by Dr. Paul Moure and Dr. Etienne Sorrel, Prosecutors to the Faculty of Medicine, Paris, Médecins Aide-Majors de 1er Classe, Surgeons to the French Hospital at Jassy.

April 5th, 1919: (1) Nervous Complications of Exanthematic Typhus, by A. Devaux, formerly Interne of the Paris Hospitals, Médecin-Major de 2me Classe. (2) Note on the Epidemic Diseases Observed in Rumania during the Campaign of 1916-17, by Dr. Henri Vuillet, late Interne of the Paris Hospitals.

May 3rd, 1919: (1) Malaria During the War, by G. Paisean, Médecin-Major de 2me Classe. (2) Distribution of Soldiers, Temporarily Unfit through Malaria, in Agricultural Colonies, by Professor E. Jeanselme. (3) Studies on Renal Function in Chronic Nephritis, thesis by Pasteur Vallery-Radot, reviewed by Professor Charles Achard.

June 21st, 1919: (1) Recent Work on Cerebro-spinal Fever, by C. Dopter, Professor, Val-de-Grâce, Médecin-Chef to an Infanterie Division. (2) Meningococcal Rheumatism and Arthritis, by Dr. Paul Sainton, Physician to the Paris Hospitals.

Aug. 23rd, 1919: Radiological Examination of Pseudarthroses before and after Operations of Bony Grafts, by Paul Aubourg, Professor Agrégé, Cuneo's Laboratory for Radiology. (Centre for Surgery of Bones, Hospital 75, Cannes.)

THE LANCET can be ordered through any Library in France, or through the following special agents:—

PARIS.—MASSON ET CIE, 120, Boulevard St. Germain.

EMILE BOUGAULT, 48, Rue des Ecoles.

CH. BOULANGÉ, 14, Rue de l'Ancienne Comédie.

FELIX ALCAN, 108, Boulevard St. Germain.

M. CHOISNET, 30, Rue des St. Pères.

H. LE SOUDIER, 174, Boulevard St. Germain.

MAULOINE ET FILS, 27, Rue de l'Ecole de Médecine.

VIGOT FRÈRES, 23, Rue de l'Ecole de Médecine.

MARSEILLES.—TACUSSEL AND LOMBARD, 54, Rue Paradis.

TOULOUSE.—ÉDOUARD PRIVAT, 14, Rue des Arts.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 27, 1919.

## Temporary Officers in the R.A.M.C. : The New Contract.

WE published recently the terms upon which the War Office is willing to accept the services of medical practitioners, including those who have been demobilised, who are desirous of undertaking duty with the Army. These terms are, to our thinking, so favourable that we have no hesitation in recommending young medical men to apply to the Secretary, War Office, Cornwall House, Stamford-street, London, S.E., for prompt temporary engagement. There are, indeed, two reasons why we bring forward the invitation of the War Office in what is meant to be a marked manner. The first, which we have already alluded to, is the satisfactory nature of the terms. Having only the recently qualified man in our mind, we would point out that if his application for employment for six months or a year is successful, he will have at the expense of his country an admirable opportunity for travel; he will have nothing to pay; and he will find himself at the end of a short period with £300 or £600 to his credit. It is difficult to imagine a pleasanter as well as a more instructive way of beginning professional life. But secondly, there is to our mind upon some of the newly qualified men almost an onus to assist their country in this way. The medical staffs in India, Mesopotamia, and Egypt are distinctly short, and the result is that the medical officers of the R.A.M.C., both Temporary and Territorial, have to be retained in these areas. Many of these men have surrendered practices at home to serve their country abroad, and they cannot return to those practices until efficient substitutes have been found for them. This is a very hard position for them, as well as for the War Office, whose sympathy for the practitioners in exile is quite sincere. Those at the head of the Royal Army Medical Corps frankly feel the unfairness of keeping these practitioners month after month, and, indeed, year after year, away from home, family, and a suspended career. The situation is unavoidable for the moment, as the men cannot be spared until they are replaced by others. The strain is probably temporary, new men only being urgently required for six, or perhaps 12, months; but for such a period they are needed. Some of the newly qualified men, who have not served in the Army, were absolved from combatant service in order to obtain their medical qualifications, the idea certainly being that, when they were qualified, they would be at the disposal of the country. A large proportion of these may be fairly expected to take temporary commissions now in order to relieve their seniors in the profession, many of whom have served during the last four or five years at great personal sacrifice and in circumstances of high risk. This is still a patriotic call, for the position in the R.A.M.C., as elsewhere, depends on the fact that war conditions do not and cannot cease at the moment of the declaration of peace.

## A Defence of Urbanisation.

URBANISATION has been credited with many ills. At every period of life it has been blamed—and, doubtless, rightly blamed—for its maleficent influence. In infancy, for a heightened mortality from zymotic enteritis and the exanthems; at school age, for affections of the nose and throat, and for dirt diseases in general; in adolescence, for the rapid spread of venereal maladies; in adult life, for alcoholism, hyperpiesis, neurasthenia, and phthisis. It takes some courage, therefore, to break a lance in favour of urbanisation, as has been done by Lieutenant-Colonel A. G. LOVE, U.S.M.C., and Professor CHARLES B. DAVENPORT in the *Archives of Internal Medicine* for August, 1919, who boldly contend that life in urban communities produces a general resistance to disease. This opinion is based upon a study of the immunity of city-bred recruits observed during the last four months of 1917 in the 16 large army camps of the United States of America. It rests upon no mere general impression, but upon the records now available in the Medical Department of the U.S. Army, which they have analysed with the equipment of practised statisticians.

The population of the camps consisted of men at ages from 21 to 30 years, taken from their homes and placed in barracks where they slept in beds only some few yards apart, or in tents where they often had an average floor space of less than six square yards. Men from rural districts had, for the most part, never lived thus congestedly, and it was to be expected that their reaction to the new environment should be different from that of town dwellers. The authors report in detail on the incidence of the six principal communicable diseases—measles, mumps, pneumonia, cerebro-spinal fever, scarlet fever, influenza—in the various camps according to their "urbanity," that is to say, according to the proportion of their population drawn from urban communities. The results were similar in each case. We give the actual words of the report in regard to measles, which within three months provided 47,000 cases to study among the enlisted men:—

".....the incidence of measles varied greatly in the different camps. This ranged in 1917 all the way from a mean annual admission-rate of 500 per 1000 at Camp Wheeler, Ga., to about 1 at Camp Wadsworth, S.C. The climatic and housing conditions at these two National Guard camps, located about only 100 miles apart, were very similar. Measles was present at both camps. The tremendous difference in the history of the epidemic seems clearly to be due to a difference in the constitution of the population. The soldiers at Camp Wadsworth were seasoned National Guard troops from New York City and vicinity. The soldiers at Camp Wheeler were mainly newly inducted National Guard troops from Alabama, Florida, and part of Virginia, sparsely settled States."

Put into technical language, the correlation between (1) the proportion of men in the Army born in any State who were admitted to sick report for measles, and (2) the urbanity of their respective native States, was found to be —0·80—a high correlation as correlations go, but inverse (as the minus sign signifies), meaning that the more urban the native State the less susceptible to measles its native-born sons in the Army. The correlation figures for the other epidemic diseases were found to be: mumps, —0·58; pneumonia, —0·37; cerebro-spinal fever, —0·44. What held for measles held in large degree for the other members of the group.

Turning to the explanation, the obvious hypothesis is the one formulated by Surgeon-General

GORGAS himself that (almost in the words of the old riddle) the recruits coming from densely populated areas were immune from measles and mumps because they had had them. Good so far as it goes, but inapplicable to scarlatina, pneumonia, and cerebro-spinal fever. The second hypothesis, that a selective elimination of susceptible individuals has occurred in the urban areas, is also turned down by the authors as not fitting mumps. Mumps does not kill off New York children. A third hypothesis of increased susceptibility in the south for exanthems, as for malaria and hookworm, has no basis in experience or experiment. The only remaining hypothesis is that to which the authors give their adherence, and which we have already enunciated: a general increased resistance to disease enjoyed by urban dwellers. They go on to give a closely reasoned support of the related assumption that any one of the communicable diseases leaves the body in a state of heightened resistance to all micro-parasites. Arising out of the work of J. W. JOBLING and W. PETERSEN<sup>1</sup> in America it will be fresh in the minds of our readers that Sir ALMROTH WRIGHT<sup>2</sup> drew this "collateral" immunisation as one of the pathological lessons of the war, a conclusion to which experience had been pressing him ever since the allegation, made before the Indian Plague Commission 20 years ago, that antiplague inoculation had cured eczema, gonorrhœa, and other ills. A number of quite trite observations point in the same direction: the city dweller's immunity from habitual catarrh which attacks him at once on his return from a long holiday in pure air; the added risk of a post-mortem prick at the end of the long vacation. It may not be much, but urbanisation has something to be said for it

### Nurse Anæsthetists.

To use the best that was available was the war maxim, and among other directions the maxim has been applied to anæsthetics, with the result that on many occasions it has proved expedient to utilise the services of the nurse as anæsthetist. Concerning this procedure, in reply to a query, "What do you think of nurse anæsthetists?" addressed by Brigadier-General FINNEY and Colonel G. W. CRILE to the American Base Hospital staff, the answers received were: Very satisfactory, 25; satisfactory, 8; unsatisfactory, 1 (for prolonged operations). It may fairly be deduced that the makeshift gave results agreeable to American surgeons under war conditions. In America, Switzerland, Uganda, the nurse anæsthetist is accepted; she found a place in some of our own hospitals during the war. Is this the beginning of a practice which may become the rule? There is no question that the usual rule-of-thumb technique can be acquired by any nurse of average intelligence, and that after proper instruction she can learn to induce anæsthesia slowly, to prevent respiratory complications, to maintain regularity of dose and therewith of depth of anæsthesia, and to give the needed relaxation. Is this enough for the safety of the patient and for the ease of mind essential for the operator, if he is to exercise all his skill? An anæsthetist is a pilot, who steers the ship of life over a reef-abounding sea to the port of safety. His eyes must be trained to detect dangers at a distance and, ever on the alert, he must spy out rocks before the

vessel has touched them. His motto should be: "Me duce, tutus eris." Kismet has no place in his vocabulary. Can the non-medical though trained nurse reach this standard? If not, is it wise to introduce a less equipped order of practitioners, as nurse anæsthetists would be, when, if proper encouragement were given, a sufficient number of qualified doctors, men and women, would take up anæsthetics as a specialty?

In support of the claims of the trained nurse as an anæsthetist it has been pointed out that although nitrous-oxide-oxygen as a routine anæsthetic for long operations counts as dangerous, yet CRILE and LOWER report close on 35,000 cases without a fatality, a nurse in most cases administering the anæsthetic. In 1916 the authorities of Charing Cross Hospital, having decided to broaden the basis of the nursing curriculum, introduced a series of lectures on anæsthetics, including the preparation and observation of patient, general principles, methods, post-anæsthetic sequelæ complications and their treatment. These lectures have since been published in book form,<sup>1</sup> and mark a move in the right direction of education, although difference of opinion may arise in regard to the remark:

"It is a question whether surgical sisters should not have practical instruction in administering anæsthetics. We move slowly here and guardedly. Our laws are strong to endure, but hard to alter. Many signs seem to me to indicate the approach of a day when chosen nurses will, in their final year, be taught not only the science but the art of anæsthesia."

No one would doubt the desirability of teaching the nurse to give an emergency anæsthetic in case a professional administrator should be unprocureable, and the example of Charing Cross Hospital might with advantage be noted in the curriculum of the Central Midwives Board. When a midwife obtains medical aid for difficult labour, she gives the anæsthetic, but, be it remembered, whatever her ability the doctor is responsible. Some measure of instruction for the midwife would stand him in good stead here, but those who advocate the innovation are, we hope, not blind to the risky side of the advice.

The administration of anæsthetics is not merely the putting of a patient to sleep. The selection of the method and means to be employed in a surgical case are now arrived at after an exchange of opinion between operator and anæsthetist. The surgeon states what he wishes to do, and the anæsthetist, after examination of the patient, suggests how he proposes, with due regard to the patient's condition, to meet the surgeon's needs. The operator, engrossed in his own work, cannot watch the progress of the anæsthesia; for this the anæsthetist is responsible. Even so casualties do occur, and at trivial operations. Would they not be more frequent with a less skilled type of administrator? The position may perhaps be put fairly thus: Trained nurse anæsthetists would do in England as excellent work as they have done in the States or elsewhere; complications must, however, occur; with these the doctor anæsthetist must be able to deal more efficiently than the nurse. Extreme advocates for the latter have said in effect: Doctors order medicines, but they do not administer the dose themselves; with the inference, the operator orders chloroform or ether, it can be dropped on a bit of gauze held over the patient's face by a nurse under the surgeon's direction. There may be surgeons who still desire to be chief of the anæsthetic, as well as of the

<sup>1</sup> Journ. A.M.A., June 3rd, 1916; Arch. Int. Med., June, 1917.

<sup>1</sup> Anæsthesia and the Nurses' Duties, by the late A. de Prenderville. LL.B., M.R.C.S.

operating field, but they must be very few. So few that the argument falls. The tendency of the time is to give high credit to the anæsthetist's function, and the suggestion that there is a widespread wish to follow the procedure of certain American centres is ill-founded. On the contrary, American and continental doctors have expressed their admiration for English methods of anæsthesia. At a well-known throat hospital three American specialists recently stated that they employed local anæsthesia for submucous resection because of the difficulty and danger of a general one. They admitted that the operation could be done much more thoroughly, as it was in England, the patient being unconscious. In an address delivered in May, 1915, at Cincinnati, Dr. EMMET F. HORNE remarked that many men in America were beginning to devote all their time to the study and administration of anæsthetics, as had been done in England for many years, with far-reaching results. It is, of course, possible that with such intensive study the traps and pitfalls of anæsthesia may be removed and the way smoothed for the less expert. Analogy does not make this likely.

## Annotations.

"Ne quid nîmis."

### MALARIA IN THE UNITED STATES.

A PAMPHLET dealing with various aspects of the malaria problem in America has recently been published by F. L. Hoffman, LL.D., statistician to the Prudential Insurance Company of America, and chairman of the Subcommittee on Statistics of the National Malaria Commission, who is already known as the author of "A Plea and a Plan for the Eradication of Malaria throughout the Western Hemisphere." The pamphlet is a consolidation and revision of a number of papers read by the author before certain public bodies during the last two years in the course of a campaign against malaria in the United States. He gives a number of interesting facts and figures concerning the disease and the measures he advocates for its suppression. It appears that there are three principal well-recognised endemic areas of malaria in the United States—one large and two small. The first and largest covers the whole south-eastern portion of the States, its southern boundary being the Gulf of Mexico; its western boundary is a line drawn from Eagle Pass on the Rio Grande to Leavensworth, Kansas; the Atlantic seaboard is its eastern boundary, and its northern is a line drawn from Leavensworth, Kansas, eastward some distance north of the Ohio river and extending to the Atlantic on a line with the northern boundary of Maryland. The second area includes a section of the northern part of New Jersey, southern New York State, Connecticut, Rhode Island, and part of Massachusetts. The third is situated in California and comprises the Sacramento and San Jaquin Valleys. Dr. Hoffman endorses the statement that the success of malaria prophylaxis is very largely a question of local conditions and the assistance given by the local and central health authorities. He sets out four different methods which should be applied in conformity with the variations in the local conditions, since a method which may be most useful in one locality may not

be so useful in another. The methods recommended, not necessarily in the order here given, are the usual ones: (1) the prevention of the development of the plasmodia in man and their destruction in infected individuals—both of these aims are accomplished by the administration of quinine (that is, quinine prophylaxis); (2) destruction of the mosquitoes transmitting malaria; (3) protection of man from the bites of mosquitoes; and (4) education of the public regarding malarial prophylaxis. In recent years, fortunately, the mortality from this disease in America has been on the decline. The case mortality rate is higher in the coloured population than among the whites. For the two-years' period 1915 and 1916 the fatality rates were 1·2 per cent. for the coloured and 0·7 per cent. for the whites. In order to get better control of malaria, Dr. Hoffman strongly advocates compulsory notification. Some boards of health have, indeed, made its notification obligatory, but these are a small proportion of the whole. So far reliance has had to be placed for the collection of morbidity statistics relating to the disease upon the procedure of the United States Public Health Service, which issues return postcards to medical practitioners asking for a monthly statement of the number of cases of malarial fever treated by them, giving particulars as to race, type of disease, and whether the diagnosis has been microscopically confirmed. The result is as unsatisfactory as such postal returns always are. Hitherto only about 13 per cent. of those receiving these postcards have sent replies, and the answers received from some districts are much more complete than the replies from others. The fuller information may be due either to the greater activity of the local health department or to the greater interest in the public welfare on the part of the local practitioners. Where the State boards of health are efficient, better results are obtained. In Dr. Hoffman's opinion the completeness of the notification of disease may be taken as a fairly dependable index of the efficiency of the Health Department and of the sanitary knowledge and training of its personnel. He regards the neglect of notification by general practitioners as a very serious dereliction of duty, and those who thus fail in the discharge of what is a public service "should be punished according to law to the fullest extent." He would treat with equal severity any local or State board of health which is unwilling to enforce the notification of malaria or other communicable disease, and adds that "incompetent officials should be dealt with according to their deserts." He further states that owing to the regrettable inadequacy of the notification returns of malaria the data published by the Public Health Service in their present forms cannot be utilised to much practical advantage. There is much that is useful and instructive in Dr. Hoffman's pamphlet.

### INDUSTRIAL FATIGUE AND ACCIDENTS.

Two further reports<sup>1</sup> have just been issued by the Industrial Fatigue Research Board. Dr. H. M. Vernon's illustrated description of the millmen's work in tinsplate manufacture, his investigations into the influence of hours of work and of ventilation on the output, and his suggestions of improvements in factory appliances and methods

<sup>1</sup> Reports of the Industrial Fatigue Research Board. No. 1: The Influence of Hours of Work and of Ventilation on Output in Tinsplate Manufacture. No. 4: The Incidence of Industrial Accidents upon Individuals, with Special Reference to Multiple Accidents. Published by H.M. Stationery Office, 1918. Price 6d. each net.

and in clothing, all indicate very clearly not only how arduous a task is the making of steel sheets, but also what can be done by employers to increase production and at the same time to reduce the discomfort, the fatigue, and the dangers to health of the employees. He finds an increase in total output of 8·3 per cent. when six-hour instead of eight-hour shifts are worked. His data indicate the possibility of still greater improvement in output by the installation of thoroughly efficient ventilation. He points out that the men stream with sweat within a very few minutes of starting work, that they are far more subject to rheumatism and neuralgia than various other classes of manual workers, and that throughout the shift they wear the same trousers and pants in which they journey to and from the works. He suggests several improvements, already adopted in certain American mills, which would conduce to diminution in needless physical effort and to lessened fatigue. One of the recognised consequences of undue fatigue is an increase in the frequency of factory accidents. Dr. Major Greenwood and Miss H. M. Woods, however, find in their report evidence of another factor in the determination of such accidents which has hitherto escaped attention. Certain workers are found to show a special susceptibility to accidents. They should, for their own sake and for that of their fellow workers, be transferred to less risky occupations. Further inquiry is obviously needed to discover what are the reasons and the remedy for such susceptibility. It may be that the individuals in question are unusually careless, nervous, or clumsy. At present we are quite ignorant of the cause or causes. The psychological examination of the susceptible worker would prove an interesting and valuable piece of future research.

#### THE PRINTED LIE.

LATELY a distinguished layman, reviewing the results of the war, remarked that the chief thing it had proved was the power of the lie to mould public opinion. This hardly comforting finding might have been foreseen. In the sphere of science error wilfully propagated is rare, but in the troublesome business of governing men it is, up to date, almost inevitable; as mordantly shown by Swift, and (to put the lady in very good company) in Vernon Lee's account of "vital lying." One reason why science is so much freer from falsehood than politics is that those interested in the former, being better educated, are much less credulous of what they see in print—having, indeed, constantly before them the garbling of scientific matters in the daily press. But the ordinary citizen, who has time and inclination for one newspaper only, believes its calumny by commission and omission just as readily as its reports of football matches. Again, in science, dealing as it does with exact and rational matters, truth prevails much more quickly than in the uncertain domain of the human heart and will. Nevertheless, the lie has been met with in medicine. The not rare phenomenon of patronised professors writing to order is little seen, although some perverseness to social influences may exist. But there is danger of it when millionaires endow and maintain a large organisation for research, especially considering the direction of the sociological trend of sanitary science. Merciful deceiving of a moribund patient is not an instance in point, if only that every wise

practitioner safeguards himself by enlisting the coöperation of the patient's relatives, whom he leaves in no doubt as to the facts of the case. Where the written lie is chiefly operative is on the commercial side. Very few baseless medical certificates of physical incapacity for war service came to light, although, of course, some must have remained undetected, the responsibility for them occasionally being on the shoulders of men of high professional position. The public estimation of medical certificates is, indeed, on the whole, high. Articles written ostensibly to serve research, but really in the interests of the vendors of some drug, appliance, or bacterial derivative, have been dealt with by medical organisations in more than one country. Such communications cannot be hard to detect by the fairly experienced, but they do much harm. The sacred thirst for truth is the motive of all fruitful research, and although an upholder of a dying theory or remedy (generally the latter) may write, as Samuel Johnson sometimes talked, "for victory," it is mostly unconscious, not deliberate, mental bias which puts a man into this posture. In science, which represents a high triumph of human culture over nature—which is, of course, non-moral to the core—truth reigns as nowhere else. Here especially does the American writer's epigram hold good that truth will survive being run over by a locomotive, while error dies of lockjaw if it pricks its little finger. And although these last five years have indeed shown that to political lying and vital lying must be added a third variety, to wit, war lying, yet happily from the severe injuries truth has sustained she is now slowly making sure recovery.

#### GANGRENE DUE TO CARBON MONOXIDE POISONING.

IN the *Journal of the American Medical Association* of August 30th Dr. J. E. Briggs has reported a case of a very unusual complication of carbon monoxide poisoning. The case is of interest not only on account of the rarity of the complication, but because it shows the danger, which is not generally recognised, of exposure to the exhaust gases of the internal combustion engine. Three brothers went for a fishing trip in a motor-boat. Before starting the exhaust pipe had been disconnected preparatory to installing another muffler. The exhaust was ordinarily carried out along the bottom of the boat, but the pipe was disconnected within 3 feet of the engine, leaving the open exhaust in the cabin, which was 15 by 7 feet. One of the brothers went to the cabin and lay down. After a time another went to arouse him, but after 15 minutes had not returned, and the third noticed through the open door that he had suddenly fallen forwards. He shut off the engine and rushed in. He found the first brother lying on the floor about 8 feet from the engine, and the second about 4 feet from it and dead. The first, who was breathing, was carried out of the cabin, and efforts were made to revive him. At first he talked incoherently. He was taken to hospital and treated for what appeared to be second degree burns of both hands and feet. His back, as well as that of the dead man, was covered with large tense blebs. These were punctured, trimmed, and dressed with boric ointment. He was discharged, but the affected areas enlarged and extensive gangrene followed. A month after the accident he was admitted to hospital under

Dr. Briggs's care. There was gangrene of the entire three middle fingers, one-half of the inner border of the thumb, and an extensive area of the little finger of the right hand. In the left hand gangrene affected the distal phalanges of the four fingers and the flexor surface of the thumb. There were also on the right side gangrenous areas on the outer border of the tibial region, the external malleolus, the outer border of the dorsum of the foot, and small patches on three toes. On the left foot were gangrenous areas at the distal end of two toes. The location and character of the lesions showed that they could not have been due to exposure to heat. The gangrene was dry, and affected skin, muscle, tendon, periosteum, and bone, and extended into several joints. Lines of demarcation were well established. Amputation of the three fingers of the right hand at the metacarpo-phalangeal joints and of the four fingers of the left hand at the middle of the second phalanx was performed. Two similar cases have been recorded. Alberti<sup>1</sup> has reported a case of extensive gangrene of the musculature of the throat and paralysis of the left leg after carbon monoxide poisoning. The patient was overcome by the gas escaping from a stove. He awoke with pains in the head, and on attempting to rise fell unconscious. Paralysis of the right foot and painful swelling of the right elbow, pain in the arm, and stiffness of the neck followed. On the right side of the neck a dry, brownish-black, mummified area of the size of the palm appeared. A line of demarcation formed. It was necessary to incise to a depth of 2 cm. before blood, mixed with dark-brown fluid, appeared. The gangrenous areas extended and he died 26 days after the poisoning. A. Maclean<sup>2</sup> has reported the case of a patient found unconscious in his room with a small gas burner open, in which the flame had been accidentally extinguished. The gas contained 7 per cent. of carbon monoxide. A week later he complained of pain in the feet and legs, and was admitted to hospital because they were swollen and discoloured in patches below the knee. During the next two weeks the pain continued, the legs became oedematous, and the discolourations became gangrenous. Both legs had to be amputated. Recovery ensued.

#### THE CENTENARY OF THE HUNTERIAN SOCIETY.

THE Hunterian Society was founded in the year 1819, and even in its early days, judging from the reports in our own columns, the discussions seem to have been attended with a vivacity unknown at other medical societies of London. To give a single example: At the Hunterian Society in May, 1826, a Mr. Waller related to a critical audience his personal experience of transfusion in the treatment of conditions of dangerous hæmorrhage. His remarks were not well received, and the president, in summing up, commented on the fact that the speaker had omitted to employ one important remedy—namely, "glysters of chicken-broth." More recent meetings, although curtailed by war conditions, have dealt with equally live topics, and a full programme is planned for the coming winter session. Meetings will be held on the second and fourth Wednesdays in the month from October to April at 9 P.M. at the School of Oriental Languages (formerly the London Institution) in Finsbury-circus. A special address by Professor Arthur

Keith, F.R.S., will be given on Oct. 8th in the Hall of the Society of Apothecaries. The Centenary Dinner takes place on Oct. 22nd, when Sir Norman Moore will propose the health of the Society. Sir William Osler has undertaken to deliver the annual oration. The present officers of the Society are Dr. W. Langdon Brown, president, Dr. F. Howard Humphris and Dr. R. L. Mackenzie Wallis, honorary secretaries. We wish the centenarian City medical society a renewed youth and vigour.

#### THE OPENING OF THE WINTER SESSION.

THE new session of the London Schools of Medicine which is upon us is likely to be noteworthy in one particular especially. It will see the inauguration of research clinics in several schools with a recognised authority at the head of each, who will devote the whole of his time and interest to the advancement of his special subject. At University College Hospital Dr. T. R. Elliott is mentioned as the director of the medical clinic; at St. Thomas's Hospital Sir Cuthbert Wallace has been made responsible for the establishment of a surgical unit; St. Bartholomew's Hospital is fortunate in finding men like Sir Archibald Garrod and Mr. G. E. Gask to preside over the medical and surgical research departments respectively. It is too early to presage the kind of development to which these appointments will give rise, although it is certain that they will enhance the reputation of the London School of Medicine as a research and teaching centre. A substantial step will have been taken towards founding that solid basis of undergraduate and graduate study in London which is befitting to a city of the size and position of the metropolis.

#### A NEW MEDICAL JOURNAL.<sup>1</sup>

THE *Journal of Industrial Hygiene* combines two innovations. This is the first serial publication devoted to occupational health, that branch of preventive medicine which is so rapidly coming to the front. Contributions to industrial medicine have heretofore appeared in publications dealing with general hygiene, medicine, or surgery; they have nowhere been collated, and those interested in the subject have had to watch all journals or run the risk of missing important papers. Secondly, it has an international editorship, American and British. This coöperation between two of the greatest industrial countries in the world is admirable, and is a sign of scientific friendship from which only good can come. The two nations are bound to be industrial rivals, but friendly rivalry is good for both; and joint action will assist in keeping it friendly, stimulate a proper emulation in effort to improve the health of both peoples, and stand ever in the way of jealous animosity. From both points of view this new venture deserves success. The journal, which in the excellence of its printing and of its reproductions of diagrams and illustrations holds out a challenge to many of our home publications, is produced by the Macmillan Company in America; hence we presume the predominance in the first two numbers of American contributions. The names, however, of those in this country who coöperate in the editorship should ensure in future numbers

<sup>1</sup> Deutsch. Ztschr. f. Chir., 1884, p. 476.

<sup>2</sup> Journ. American Med. Assoc., May 20th, 1911, p. 1455.

<sup>1</sup> The *Journal of Industrial Hygiene*, Macmillan Company, Fifth Avenue, New York.

adequate representation of British thought and research. The first number makes its bow with an article by Dr. Mock, who traces the development of industrial medicine in the States, and points out the stimulus it received during war-time. In this country, too, through the action of the Ministry of Munitions, war-time employment gave great impetus to the movement which we hope may hereafter be duly recorded. The writer sums up: "Thus, in the course of one short decade broad humanising principles, combined with scientific, medical, and surgical work, have permanently established in the medical profession this far-reaching health service—industrial medicine and surgery." Both the first and second numbers contain contributions from Dr. Alice Hamilton, who, in an interesting, if somewhat discursive, way, deals with her own specialty—industrial poisons; but in attempting to cover intoxication from lead, zinc, copper, brass, arsenic, antimony, mercury, carbon bisulphide, phosphorus, and carbon monoxide in two articles, she hardly does justice to her subject or herself. The most important paper is undoubtedly that of Dr. Spaeth on the "Problem of Fatigue." It is the best exposition of present knowledge on the subject we know, and is accompanied by an excellent and exhaustive bibliography. The author summarises laboratory experimental research and chemical knowledge of vital activity; and then proceeds to discuss practical methods of investigation in the industrial world by testing individuals and by measuring output, accidents, lost time, and sickness, all of which he holds may be expected to throw further light on definite aspects of the subject. Psycho-physiological tests are condemned as impracticable under industrial conditions; but research into reflexes and objective tests is recommended as likely to prove of value. The relation of hours of labour to efficiency is held to establish the superiority of a shorter working week, at any rate so far as the eight-hour and ten-hour shift systems are concerned; and the author holds that "the men who planned such a radical industrial programme (as the eight-hour day) were possessed of a profound wisdom and social vision." This article should be carefully read not only by medical men but by employers and employed, for it is not unknown for the workmen to desire, tempted by pay, to defy hygienic laws. Dr. Anna Richardson tells from her own experience of the value of medical service among telephone operators. This contribution should be of use to factory medical officers in indicating the work there is to do, and the way in which records can be scientifically analysed. Dr. Austen sets forth his work in examining factory employees before engagement, and points out its value. He places to the credit of efficient health service: "(i.) diminished labour turnover; (ii.) diminished loss of production, due to absenteeism; (iii.) increased efficiency and lessened cost of production, due to higher grade employees; (iv.) diminished industrial liability to accidents, due to elimination of physical and mental defectives; (v.) diminished moral hazard, due to the fact that venereal-infected employees are only conditionally employed; (vi.) diminished labour cost, due to the reduction of the excessive overhead charge which results from transferring employees who are working at a physical disadvantage; (vii.) a hospital and dispensary place employees in direct personal touch with the entire organisation, and show such

employees that their company recognises that healthy individuals are the most vitally necessary part of its success." A paper on health by an engineer, Professor Whipple, is excellent in itself, and valuable as surveying hygiene from an essentially practical point of view; the view of one who has to accomplish what the medical scientist declares should be done, whether in mosquito control, drainage systems, or factory construction. Other articles deal with "Chip Fractures of Terminal Phalanges," by Dr. Hurley; and "The Use of Army Gas Masks in Industries." Not the least valuable part of each number is a supplement giving abstracts of the current literature of industrial hygiene. Each notice is signed by the abstractor, which is likely to ensure more careful work than anonymity; and the notices are for the most part of such reasonable length that the reader can obtain a real idea of the work mentioned—a point where many abstracts of literature fail even to the extent of being little more than bibliographies. The standard maintained here is, however, uneven, and we recommend the editors to watch carefully this important part of their journal. We are so confident this journal meets a need, and has before it an opportunity of doing great and useful work, that we intend keeping our readers informed from time to time of the progress made.

#### THE COMPLEAT MASSEUR.

THE programme of the Conference of the Incorporated Society of Trained Masseuses, announced for Oct. 2nd-4th, suggests the stirring of new life. We may associate it with the petition recently addressed through the Board of Trade to His Majesty in Council begging that a Charter may be granted to a society to be known henceforth as the Chartered Society of Massage and Medical Gymnastics. The object of the proposed society is to unite together the older Society of Trained Masseuses, which was founded in 1894 and incorporated in 1900, and the more recent foundation, the Institute of Massage and Remedial Gymnastics, which was founded in 1916. Up to the time of the foundation of the Incorporated Society of Trained Masseuses 25 years ago, massage treatment in this country was in a parlous state. Anyone who chose could pose as a masseur, and training was so limited as to be almost non-existent. Small wonder, then, that the Swedish masseur became the traditional instrument to employ when ordering "massage." Thanks almost solely to the untiring efforts of the founders of the Incorporated Society and their successors—a faithful and disinterested band whose work has received all too little recognition—the art of massage was raised step by step from the lowest depths and placed upon a basis which, though still far from perfect, can only be considered as remarkably good. The lamentable lack of interest shown by the medical profession as a whole has been the main stumbling-block in the road of progress. Many medical men have studied and practised electro-therapy in recent years; there are few who would not be hard put to it if invited to carry out themselves the simplest of massage treatments, and fewer still who could write out a table of exercises applicable to a particular condition. The result is that most medical men who order "massage" or "exercises" are incapable of discerning between good and inefficient work and,

judging by results alone, are liable to extol or deprecate without discrimination.

In an article in a recent number of the *Journal of the I.S.T.M.*, Dr. Carl Westman points to the remedy. He advocates:—

(I.) "Compulsory visits for all medical students to the massage departments and opportunity for special training of those interested, such course to run concurrently with the medical studies."

(II.) "The adaptation and development of the treatment along scientific and rational lines."

The former suggestion will save the medical man of the future from ignoring one of the most valuable methods of treatment in his armamentarium. The second will then follow as a corollary. Dr. Westman goes on to advocate a revised and standardised training for masseurs (including "masseuses"), with abolition of the present six months' course certificate. It may be it is possible in six months to acquire a smattering of what is generally included under the term massage, a poor remedy on which to rely in remedial work. For surgical or orthopaedic cases a knowledge of Swedish remedial exercises is essential, the period of training required for admission to the existing examination being six months. A year's training is therefore an irreducible minimum for the fully qualified masseur. The formation of a register of persons qualified to practise massage, and the penalisation of quackery, would then protect the public from the danger of the uninstructed dabbler in remedial gymnastics. At present the gymnastic directors in this country have been trained in the two or three years' course at one or other of our leading physical training colleges. Their isolation from hospital work is the one great flaw in an otherwise magnificent training. These qualified gymnasts require recognition and protection, as well as the others who are more especially trained in medico-physical treatment. The granting of a charter should soon make it possible compulsorily to extend their training so as to embrace the full course of massage, Swedish remedial exercises, and electro-therapy.

#### THE COST OF HOUSING THE PEOPLE.

Sir Kingsley Wood, M.P., Parliamentary Secretary to the Ministry of Health, speaking at Brighton, urged his hearers to set off against the cost of modern house building the gain in health which the nation might expect as the result of better accommodation for its humbler members. This is probably the wisest, if not the only, way in which the matter should be looked at. The community has to contemplate a prospect of expenditure which, judged by the ordinary standard of probable pecuniary return, it would not be justified in undertaking. There is, however, this consolation, that the Ministry of Health, so Sir Kingsley Wood declared, was not going to be satisfied to emulate the jerry-builder of the past, and we hope to see new houses in which the saving in repairs will to some extent compensate for the initial expenditure on their production. It is to be regretted that when a man, or the nation, comes forward with money to spend and an object which has to be attained by its expenditure, he and, more than he, the nation, finds at once every one's hand against him. It will not be a hand raised in violence; its energies will be concentrated not upon taking his life, but upon emptying his pockets. Sir Kingsley Wood referred to claims provisionally made as to the price of land

for houses, amounting in the aggregate to £587,000, reduced by efficient valuation by £143,250. This is a reduction of not much less than 25 per cent. The building of houses by tender is not on quite a similar basis with the acquirement of the land for them. The cost of the houses of the class referred to was quoted by Sir Kingsley Wood as being about £700, minor details and accessories giving a certain amount of opportunity for economy to those desirous of effecting it. The audience at Brighton were reminded of the power of local authorities to contract with builders for the purchase of houses erected by the builders themselves.

#### PUBLIC-HOUSE REFORM.

THE virtues and vices of the existing licensing laws have been carefully considered by a sub-committee of the Brewers' Society and the National Trade Defence Association, who have issued an interesting draft of a new Licensing Bill this week. New licensing authorities, reduced hours of sale, and fresh penalties for inebriety—all involving somewhat drastic changes—are proposed, but the most interesting part of the Bill deals with an attempt to make the public-house a place comparable with a tea-shop or café. Too long has the liquor trade confined its business to merely the sale of liquor, and they realise now the mistake of not making the "pub." a centre of real and varied public refreshment and entertainment. Supposing that legislation should ensue upon this Bill, there will be difficulty, of course, just now in adapting existing premises to meet this much needed reform, but the policy of rendering places of refreshment airy and commodious, providing in them wholesome food and non-alcoholic beverages, is so sound that expense should not stand in the way. Moreover, money so spent would be a good investment. That the stuffy and unwholesome gin-palace and the dirty, offensive public-house must go, and decent rendezvous of refreshment substituted, has been for a long time a very general decision.

THE Home Secretary is about to appoint an inspector under the Cruelty to Animals Act. The appointment will be for a term of four years in the first instance and the salary will be £800 a year, together with war bonus on the scale authorised for the Civil Service and travelling allowances at the usual Civil Service rate. The inspector will be required to give his whole time to his duties. Candidates for this post who possess the necessary scientific qualifications required for the work should apply to the Private Secretary, Home Office, London, from whom further particulars may be obtained. Applications should be accompanied by one or two testimonials and particulars of the candidate's qualifications, and should reach the Home Office not later than Oct. 10th, 1919.

#### "THE LANCET" OF

JAN. 18TH, FEB. 8TH, 15TH, MARCH 1ST, AND  
JULY 5TH.

THE Manager will be obliged to readers who have not any further use for their copies of THE LANCET of the above dates if they will kindly return them to him at 1, Bedford-street, Strand, W.C.2. The postage on the first four numbers is one halfpenny each, and on July 5th one penny. He will be pleased to pay for those returned.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

*Death of Professor Trail of Aberdeen University.*

THE death took place at Aberdeen on Sept. 18th of Professor J. W. H. Trail, who had occupied the chair of botany at the University of Aberdeen for 42 years. Professor Trail, who was 68 years of age, was born at Birsay, Orkney, and was educated at Aberdeen University, graduating M.A. in 1870, M.B., C.M. (with honours) in 1876, and M.D. in 1879. From 1873 to 1875 he acted as naturalist to an exploring expedition in Northern Brazil. In 1877, at the early age of 26, he was appointed regius professor of botany at Aberdeen University, which appointment he held up to the time of his death, when he was senior member of the Senatus. He was a Fellow of the Royal Society and of the Linnæan Society, and had made many contributions to scientific journals on botanical and zoological subjects. Outside the University he was also well known for his activities in public life in connexion with the subject of education.

*St. Andrews University: Chair of Natural History.*

The University Court of St. Andrews unanimously appointed Dr. James Fairlie Gemmill to the chair of Natural History in University College, Dundee. Dr. Gemmill is a distinguished graduate of Glasgow University, and held there the posts of lecturer in embryology and lecturer-assistant in zoology. He was also first president of the Scottish Marine Biological Association, which he was largely instrumental in founding.

*Election of Direct Representative for Scotland to the General Medical Council.*

Dr. Michael Dewar has issued to the profession in Scotland an address, in which he offers himself as a candidate at the election to be held in November next for appointing a Direct Representative for Scotland to the General Medical Council. Dr. Dewar is a graduate of Edinburgh University, and is well known locally for his work in connexion with the National Health Insurance Bill, both as regards its terms and administration, the British Medical Association, the Central Midwives Board (Scotland), and the Medical and Dental Defence Union. Dr. Dewar stands as a general practitioner in active practice, and is in favour of—

- (1) A fairly high standard of proficiency in general education for entrance to the medical curriculum.
- (2) The compulsory inclusion in all entrance examinations of the following subjects: English, Latin, mathematics (including algebra and arithmetic), and an additional language.
- (3) The recent action by the General Medical Council in approving of the various examinations as qualifying for registration of medical students.
- (4) The maintenance and extension of the supervision of the professional examinations by the Council.
- (5) The establishment of a one portal system for admission to the medical curriculum and to the medical profession.
- (6) The total prohibition of unregistered dental practice, due regard being given to those who have been practising dentistry for some years.
- (7) The necessity for the inclusion of as many general practitioners in the Council as are allowed by the 1886 Act to assist in dealing with penal cases.

He is to address meetings of the profession throughout Scotland in various centres during the month of October for the purpose of further explaining and amplifying his views.

*Public Health (Notification of Infectious Disease) Regulations (Scotland), 1919.*

A new Order amends the form of certificate to be given by a medical practitioner under Section 3 of the Infectious Disease (Notification) Act, 1889, especially in the direction of requiring the following additional particulars:—

- Measles.*—Date of first appearance of rash.  
*Tuberculosis.*—Localisation of the disease. Occupation. Usual place of residence (if other than that given in the notification). Is patient an insured person under the National Insurance Acts?  
*Ophthalmia neonatorum.*—Date of birth. Name and address of parent or other person (if any) having charge of child.  
*Malaria and dysentery.*—Is this patient's first attack? Was patient infected abroad?  
 Sept. 21st.

Dr. Alexander Morison, of Upper Berkeley-street, London, has received official sanction for the assumption of the surname of Blackhall before his paternal surname of Morison.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*The Irish Public Health Council.*

THE personnel of the Irish Public Health Council "was announced last week in these columns. Its duties under the Ministry of Health Act are "to give advice and assistance, and to make proposals to the Chief Secretary in connexion with his powers and duties under this Act." Your readers ought to know that the constitution of the Council is giving rise to severe criticism in Ireland on several grounds. Out of 17 members constituting this Health Council, five, so far, belong to the medical profession. The nominees of the Irish Insurance Commissioners (to be three in number) and of the Local Government Board for Ireland (also to be three) have not yet been made public, beyond the official chairman of each of these bodies. But it is probable that at least one of each group will be a doctor, and we may take it provisionally that six out of the 17 members of the Irish Public Health Council will be medical men, of whom at least three will be permanent officials not now in actual practice. This conclave is to suggest to the Minister of Health in Ireland (the Chief Secretary) some plan for improving the public health of the country, and yet of 17 members there will be apparently only six doctors, three of whom are not in active practice and not one of whom has been elected by the whole body of the medical profession.

Every one of the medical members of this Irish Health Council is a Dublin resident. Considering the five towns in Ireland of over 30,000 inhabitants, Dublin, with a population of 290,638, has 445 doctors; Belfast, with a population of 349,180, has 325 doctors; Cork, with 76,122 inhabitants, has 140 doctors; Londonderry, with a population of 39,892, has 32 doctors; and Limerick, with 38,151 inhabitants, has 39 doctors. Why should one Irish city, which, albeit the capital, comes second in population, have all the medical representation on a Public Health Council for the whole of Ireland? Not only the other large towns but the countryside is ignored. Ireland, as compared with England, is largely rural, and a total of 2398 doctors are absolutely unrepresented medically on this advisory Irish Public Health Council. The Poor-law medical officers of Ireland, with their wretched pay, hard work, and uncertain position—quite different from the Dublin permanent officials—have not a single medical representative on this Council, yet who know so well as they what an inadequate and antiquated public health service there is in Ireland? Irish doctors, who want the public health of the country improved, are asking how could six doctors, three not in practice and all residing in Dublin, tender advice—based on personal practical experience—in reference to the problems of the great rural districts of the centre and south of Ireland, of the "congested areas" of the west (somewhat analogous to the sparsely populated parts of the highlands and islands of Scotland, and of parts of Wales), and of the industrial public health difficulties of the north of Ireland?

*Londonderry Water Queues.*

The supply of water to Derry is daily growing less. The reservoirs on Sept. 18th had only 30 million gallons of water; one portion of the city is actually dependent on a pump, which may break down at any moment. In other parts there is a reduced supply given only twice a week, and the inhabitants there have to rely on a spring at the asylum in Strand-road, where in the 1911 water famine a pump was erected, and to this pump, an oasis in the desert, the travelling caravan of thousands of men, women, and children daily flock for water, which they carry off in every kind of vessel, from tins to whisky kegs, kettles to barrels. The corporation, in their efforts to keep some regulation of the "dry" crowd, have posted up the following notice: "Take your place in the line and wait your turn." There is a crowd both by day and night, and carts and lorries are being utilised to carry supplies. As for Belfast, there is still considerable shortage in the store of water, the total amount in the reservoirs being 1133 million gallons, as against 1609 million gallons in the same week of September, 1918. Until the water authorities in towns learn and act upon the principle that it is for dry and not

wet seasons they must prepare, such famines as at present prevail in the water-supply of their areas will every now and again occur.

#### *Scarlet Fever Outbreak in Belfast.*

There has been in Belfast a very widespread epidemic of scarlet fever since the beginning of the present month, so that now Purdyshurn Fever (Memorial) Hospital is full up (300 cases), and there are close on 100 cases more in the Union Fever Hospital. The patients are from all parts of the city and from all grades of society. There are 17 cases of scarlatina in Coleraine in the fever hospital, and the outbreak is prevalent in Kilrea, co. Derry.

Sept. 22nd.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Increase of Rabies in France.*

CASES of rabies are becoming more and more numerous in France because of the large numbers of stray dogs in the districts laid waste by the enemy. Many warnings recommending the provision of muzzles for dogs and their restraint on a leash have been issued. These suggestions, however, have not been generally adopted. Dr. Roux, director of the Pasteur Institute, at the last session of the Council of Hygiene and Health of the Seine Department, submitted to the Prefecture of Police an urgent note pointing out the gravity of the danger. He recommends that all people bitten by any sort of dog should come immediately to the Pasteur Institute. The few failures of antirabic treatment are due only to delay in treatment. Rules as to stray dogs and wearing of muzzles should also be enforced with vigour. If the public were not so sentimental about dogs, he says, and if the law were administered more strictly, rabies would have disappeared from France by now as it did practically before the war. M. Roux quoted the example of England, where rabies was unknown, thanks to strict rules, until the day when dogs were smuggled in by air.

#### *A New Chair in the Faculty of Medicine of Paris.*

A Chair of Laryngology has just been created in the University of Paris. Hitherto the only professor of this subject in France has been Professor Moure, of Bordeaux; elsewhere the teaching of laryngology has been undertaken by assistants appointed by the professor of general medicine in the practical clinics. The new professor is Dr. Sebileau, supernumerary professor, member of the Academy of Medicine, and surgeon of the Lariboisière Hospital, where he conducts a large department of laryngology.

#### *The Raising of the Official Tariff for Doctors' and Chemists' Fees for Industrial Accidents.*

The general rise in the cost of living and of all salaries has necessarily led doctors to raise their fees, but not in proportion to the increase in prosperity of workmen, manufacturers, and business men, because medical men cannot form a professional union, nor can they refuse to attend patients when humanity calls. The public would not extend to them the tolerance allowed to strikers who stop traffic—trams, trains, or taxis—or cut off the supply of water, gas, or electricity. Moreover, in certain cases medical men are bound by a contract accepted before the war. In this category comes medical attention given to workmen's injuries, to old people, and to the poor—under the law relating to gratuitous medical aid. The charges are regulated according to an old tariff, which is not remunerative because it is calculated by the State in accordance with the insurance companies, whose terms are somewhat lacking in generosity. This old tariff, which provided a fixed sum for each category of accidents and for every sort of medical aid, has obviously become too low for present conditions of life. It has become even more unjust, inasmuch as the companies have raised their insurance rates considerably. The difference is thus entirely in their favour. The Union of Medical Councils in France have undertaken a vigorous campaign to raise the medical fees in this tariff, and has succeeded in convincing the Parliamentary commission charged with the reconsideration thereof. Henceforward all fees are to be doubled. The new tariff comes into force as from April 1st, 1919, except for bills actually paid before the law was passed (July 30th). There is thus no means of

raising the prices on their hills, if they apply to accidents sustained before April 1st next. On the other hand, the tariff is provisional, and is only valid until Jan. 1st, 1920, after which it will be subject to quarterly revision if one of the parties—the State or the Medical Councils—demands a further modification. Thus the result obtained by the Union of Medical Councils is quite important, although still insufficient, in the opinion of many doctors, as workpeople's wages are not double but three or four times what they were, and the insurance companies have raised the rates in exact proportion to the increase in salary.

Sept. 29th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

#### *The Influenza.*

THE influenza epidemic still continues to show little alteration in Victoria. A recrudescence has been noticeable since the very cold weather began, early in June, and there are still upwards of 1200 to 1500 cases as a daily hospital average in the metropolis, and an unknown, but very large, number of cases elsewhere. On the whole the case-mortality appears to be somewhat small, but there are from 10 to 12 deaths daily in Melbourne. In Sydney there was a very severe outbreak during June and the early part of July, and the mortality assumed serious proportions during one or two weeks. The banks were so short-staffed that they only opened for two hours daily. With a warm spell in the middle of July the spread rapidly subsided, and at present is well within the capacity of the existing provision. In Perth there have been a few cases, but the disease has not assumed alarming features. All inter-State quarantine has been abandoned except by Tasmania, but as there is no communication between it and the mainland, owing to the shipping strike, this is no inconvenience. The Commonwealth Quarantine Department has announced the issue of a serum for the treatment of the affection, but the general attitude is apathetic towards such methods after the failure of vaccine inoculation which may now be taken as established, at all events, for those vaccines which were employed.

#### *Medical War Relief Fund.*

A movement has been set on foot by the Federal Medical Committee and the New South Wales Branch of the British Medical Association to establish a fund to be applied to medical men, or their dependents, who have suffered financial reverse while on active service. Clauses 4 and 5 of a draft agreement which has been adopted by all the State branches provide that the fund "shall be used in assisting medical officers who have been disabled and the dependents of those who have died; and that the fund shall also be used to issue loans, with or without interest, to medical men who, on account of war service, may require temporary financial assistance." It is proposed to raise the sum of £50,000, if possible, by voluntary contribution. The weak spot in the proposal is that apparently no attempt has been made to ascertain the probable demand that may be made, which could have been approximately arrived at without much difficulty, as the proposal has only been shaped since the armistice and practically all the medical officers are traceable.

#### *Returned Medical Officers.*

The medical officers who went from Victoria on overseas service have formed a society for the promotion of the interests of its members. They approached the Premier with a request that their secretary should be supplied in advance with particulars of proposed Government medical appointments, and that all such appointments made during the war should be reviewed with the prospect of giving them to returned men. The Premier saw no difficulty in the first request, and promised to think over the other.

#### *Munificent Bequests.*

Sir Samuel McCaughey, who recently died in New South Wales, was a pioneer of the pastoral industries in Australia, and acquired a large fortune. By his will the cause of medical education should benefit, for the Sydney University receives a sum of £400,000, while the Brisbane University benefits to the extent of £250,000. The late Sir Samuel McCaughey was a bachelor.

*Personal.*

Mr. G. A. Syme, F.R.C.S. Eng., having reached the retiring age, has relinquished his position as surgeon to the Melbourne Hospital and received a special acknowledgment from the committee of his long and faithful service. Mr. Syme volunteered for overseas war duty, and worked on a hospital ship during the Anzac landing, but contracted a poisoned hand, and after a dangerous illness was compelled to proceed to England, where he acted as consulting surgeon to the Australian medical establishment. Mr. Syme is succeeded by Mr. B. T. Zwar, who also was on active service with the Australian forces.

Lieutenant-Colonel N. F. Fairley has been appointed assistant director of the Eliza Hall Research Laboratory at the Melbourne Hospital. He is a Melbourne graduate, and has done interesting work on cerebro-spinal fever and on bilharziasis.

August 5th.

## TUBERCULOSIS.

*The Welsh National Memorial.*

ACCORDING to the report of the King Edward VII. Welsh National Memorial Association, which was presented at the seventh annual meeting on July 26th, the work of the association has gone successfully forward in spite of the war. At the end of July, 1914, the association possessed 87 hospital beds. The number of sanatorium beds belonging to the association in this year was 148. By 1919 the number of hospital beds had risen to 473, and that of sanatorium beds to 594. In the year ending March 31st, 1914, the patients examined numbered 8763. In the year ending March 31st, 1919, they numbered 12,260. During the war, up to this date, no less than 11,402 had received treatment in hospitals, and 6373 in sanatoriums. More than 50,000 patients were examined at dispensaries and visiting stations by tuberculosis physicians. Since 1915 there had been no delay in making provision for discharged Service men suffering from tuberculosis; more than 2500 passed through the hands of the association's medical staff, and more than 1600 received treatment in hospitals and sanatoriums. As many as 350 patients took their discharge against medical advice, and 53 were discharged for breaches of discipline. The two large sanatoriums, Talgarth and Llangwyfan, have been almost completed, and the work of the building committees has come to an end. The medical policy of the association is discussed in a special section of the report, and many recommendations are made as to the organisation of the campaign against tuberculosis. This section deals with principles and ideals rather than with actual achievements. In presenting the report the president, Major David Davies, said that it had been decided that the appointment of chief medical officer to the association, in succession to Dr. Marcus Paterson, who resigned two years ago, had been held in abeyance during the war on account of the difficulty of securing the best man. He added that the suggestion had been made that a chair of Tuberculosis should be established in the Medical School of Wales, and that the professor of tuberculosis should become the chief medical officer of the association. In this way the close co-operation of the school and the association would be secured, and the information gathered by the association would be at the disposal of the hundreds of medical students passing through the medical school.

*Sanatorium Reports.*

The thirty-fourth annual medical report of the *Trudeau Sanatorium*, published by itself, not with the general report already reviewed in THE LANCET for July 26th, consists largely of reprints of articles published by members of the Trudeau School in the *American Review of Tuberculosis*. It contains, however, a previously unpublished account of investigations made into the subsequent fate of patients who had been discharged from the sanatorium 20 years or more earlier. Of the 814 patients traced, 148, or 18.2 per cent., were alive; 666, or 81.8 per cent., were dead. An attempt is also made to show how the severity and extent of the disease at the time of treatment affects the ultimate fate of the patient.

The report of the *Vejlefjord Sanatorium* for 1918 includes a paper by its medical superintendent, Professor Saugman, on thoracoplasty. This operation, he has found, greatly

improves the prognosis for patients in the later stages of pulmonary tuberculosis, the results of treatment for these patients being far better than in earlier years when compression therapy was not practised. The majority (64.9 per cent.) of all the patients were in the third stage, and only 10.5 per cent. were in the first stage of the disease. The proportion of patients discharged fit for work was 49.7 per cent., as compared with 44.7 per cent. representing the average for the years 1900-1918. This improvement was chiefly due to the better results among the patients in the third stage, as great a proportion as 33.3 per cent. being discharged fit for work instead of 25.4 per cent. in earlier years. Of the patients in the third stage 45 underwent treatment by artificial pneumothorax (11 failures on account of pleural adhesions) and 16 underwent thoracoplastic operations. The results in some of these cases were strikingly successful.

*The American Review of Tuberculosis.*

The May number begins with a paper by Dr. Paul A. Lewis on the Complement-fixation Test in Tuberculosis. He finds that the numerical relations are such as to make it unsafe to apply this test to the diagnosis of tuberculosis except as a matter of the most limited confirmatory interest. In a paper on the Influence of Protein Intoxication on Tuberculosis in Guinea-pigs Dr. Allen K. Krause and Dr. H. S. Willis show that repeated daily injections of (homologous) tuberculo-protein and (heterologous) egg albumin, before experimental infection with tubercle bacilli, probably render guinea-pigs less resistant to tuberculous infection. Dr. A. L. Bloomfield and Dr. J. G. Mateer give an account of cutaneous tuberculin tests carried out in 19 consecutive cases of influenza. They found that during the febrile stage of the influenza the skin sensitiveness to tuberculin was absent in every case but one. During convalescence reactivity returned to 89.4 per cent., which corresponds with the proportion of positive reactions among otherwise healthy individuals. The authors note that, in its influence on the cutaneous tuberculin test, influenza bears a striking resemblance to measles. In a paper on the Pneumothorax Treatment of Acute Lung Abscess Dr. B. Goldberg and Dr. M. Biesenthal publish three cases successfully treated. Their analysis of 16 cases thus treated, including their three cases, shows that recovery was effected in 75 per cent., improvement in 12 per cent., while two patients (12 per cent.) were dead. Their comparison of this operation with other methods suggests that artificial pneumothorax is the best procedure. A somewhat discursive paper on the Treatment of Tuberculous Cervical Adenitis, by Dr. W. R. Abbott, is a plea for tuberculin treatment.

## URBAN VITAL STATISTICS.

(Week ended Sept. 25th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.0, 10.7, and 10.4 in the three preceding weeks, rose to 10.9 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 11.4, or 0.5 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 1.8 in Enfield, 4.9 in Oxford, and 5.7 in Northampton, to 18.4 in Middlesbrough, 19.0 in Tynemouth, and 20.6 in Great Yarmouth. The principal epidemic diseases caused 434 deaths, which corresponded to a rate of 1.4 per 1000, and included 322 from infantile diarrhoea, 38 from diphtheria, 31 from whooping-cough, 25 from measles, 14 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 3.6 per 1000 in Tynemouth. The 322 deaths from infantile diarrhoea were 81 in excess of the number in the previous week, and included 103 in London, 25 in Liverpool, 12 each in West Ham and Middlesbrough, 11 in Birmingham, and 9 in South Shields. There were 1524 cases of scarlet fever and 1118 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1504 and 1057 respectively at the end of the previous week. The causes of 26 deaths in the 96 towns were uncertified, of which 3 were registered in Birmingham and 3 in Liverpool.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 10.9, 10.8, and 10.2 in the three preceding weeks, rose to 10.5 per 1000. The 224 deaths in Glasgow corresponded to an annual rate of 10.4 per 1000, and included 15 from infantile diarrhoea, 3 from diphtheria, 2 from whooping-cough, and 1 each from enteric fever, measles, and scarlet fever. The 66 deaths in Edinburgh were equal to an annual rate of 10.2 per 1000, and included 2 from infantile diarrhoea, and 1 each from scarlet fever and whooping-cough.

*Irish Towns.*—The 97 deaths in Dublin corresponded to an annual rate of 12.5, or 4.8 per 1000 below that recorded in the previous week, and included 9 from infantile diarrhoea, and 1 each from enteric fever, scarlet fever, and diphtheria. The 111 deaths in Belfast were equal to a rate of 14.4 per 1000, and included 8 from infantile diarrhoea, 6 from scarlet fever, and 1 from diphtheria.

## CONTROL OF VENEREAL DISEASES.

*Prophylaxis against Venereal Disease.*

IN January last an Inter-Departmental Committee was appointed by Dr. Addison to consider the risks of demobilisation to the health of the civilian population of the country and the measures to avoid them. A Note (Cmd. 322. H.M. Stationery Office. Price 3d.) has now been presented to the Minister of Health reporting on one small part of the venereal problem—namely, the advisability of encouraging the sale of “packets”—i.e., the provision before exposure to infection of means of prophylaxis for use either before or after exposure. The Committee heard the experience of distinguished medical representatives of various sections of troops—namely: for Canada, Colonel J. G. Adami and Colonel J. A. Amyot; for Australia, Lieutenant-Colonel G. Raffan and Sir James Barrett; for New Zealand, Major J. Falconer Brown; for the United States, Colonel A. M. Whaley, Colonel H. Young, and Colonel W. T. Snow; for the B.E.F., Major C. T. White. In addition evidence was given by Lady Barrett, Sir Bertrand Dawson, Sir H. Bryan Donkin, Sir William Osler, Dr. Morna Rawlins, Sir G. Archdall Reid, and Dr. Agnes Savill. Memoranda submitted by these experts are given in the appendix to the Note, while in the text are set out the figures of incidence of venereal disease among the different troops. The general conclusion reached by the Committee is short and crisp:—The official application of a packet system to the civil community is neither desirable nor practicable. Paragraph 8 of the Note, which is the chief justification of this conclusion, runs:—

“..... while certain drugs and preparations may be relied upon to remove or destroy the infection of venereal disease if applied by skilled attendants very shortly after exposure, such satisfactory results cannot be secured if those drugs and preparations are used unskillfully or too long a time after exposure. .... experience indicates that, however careful the instruction, and however scientifically effective the prophylactic in itself might be if used under proper conditions, it frequently fails to protect when applied by the individual, even when this self-application is supported later by additional skilled treatment. The consumption of alcoholic liquors, carelessness, natural excitement, forgetfulness, or ignorance has been the cause of numerous failures, even amongst those troops where the use of such prophylactic measures has been most efficiently organised and taught.”

The Committee, it is added, set out to examine the evidence placed before them from the scientific and the medical point of view, and it is strictly in this spirit that they desire to record it as their opinion that the irreplaceable effect of the moral factor has been too frequently neglected or forgotten.

The Note is of value if only for the definition of certain terms adopted (“for the purpose of the Committee”) to avoid ambiguity.

*Prophylactic treatment* to connote the issue of drugs and appliances made available before exposure to infection, for use by the individual.

*Early preventive treatment* to connote treatment applied immediately after exposure to infection.

*Abortive treatment* to connote treatment applied immediately on the appearance of symptoms with a view to cutting short the duration of the disease.

The adoption of this nomenclature will clarify future discussion of the subject.

*Legislation against Venereal Disease in Sweden.*

We published in 1915 and 1916 a series of annotations dealing with reforms which were then being advocated in connexion with venereal disease in Sweden. Some of these have now materialised, and in the Swedish journal, *Dagens Nyheter*, Bureauchef Sigurd Ribbing has given an account of the new law dealing with venereal disease which came into force on Jan. 1st of this year. The system of registration and regulation of prostitutes is definitely abolished, and principles are adopted corresponding more closely with modern western sociological views. Every patient suffering from venereal disease is now entitled to free medical treatment, including drugs and, when necessary, free hospital treatment. The special wards hitherto set apart for venereal disease are abolished, so that no invidious distinction is made between venereal and other diseases. Provision is made in the large towns for polyclinics, each town of over 20,000 inhabitants being obliged to provide adequate

polyclinal accommodation. To help towns to meet this obligation, the State undertakes to defray the cost of doctors, drugs, and other medical requirements, while the cost of premises, of fuel, lighting, nursing, &c, must be borne by the local authorities. In return for its substantial subsidy the State looks to the local authorities to provide good accommodation and to keep up the standard of efficiency, so as to meet modern requirements. In districts where the establishment of polyclinics is not feasible, free medical treatment is undertaken by the local medical authorities, represented by the State medical practitioners or medical officers of health. It is admitted that these medical officers do not invariably possess the skill and experience of a specialist in venereal diseases, but in thinly populated districts there has been no satisfactory alternative, and several medical officers of health, recognising their limitations, have already brought their knowledge of venereal diseases up to date by getting into touch with special hospitals for these diseases. It is also anticipated that in the near future special post-graduate courses in venereal diseases will be provided in conjunction with grants of money to practitioners attending such courses.

The new law makes it compulsory for every patient suffering from venereal disease to submit to medical treatment as long as the disease is in an infectious stage. If the medical officer's instructions regarding treatment and prevention of infection are not followed out, the patient is liable to compulsory treatment in a public hospital and to detention there until the infectious stage of the disease is passed. Any man or woman who suffers from venereal disease and who exposes others to this infection is liable to imprisonment and hard labour. And it is the duty of the authorities to prosecute without the instigation of anyone who has been exposed to infection by the accused. New powers are also given the police for dealing with brothels masquerading as hotels.

The promoters of this new law do not flatter themselves that they have even approximately solved the problems of prostitution and venereal diseases by putting the above reforms on the Statute books. Indeed, they regard these reforms merely as one step to an end that can be attained only by the greatest vigilance and by untiring supervision of the working of the innovation. It is also admitted that prostitution is an expression of certain social economic factors which are hardly touched by the new law. The war has undoubtedly swelled the ranks of the prostitute to an enormous extent by inducing poverty on the one side, opulence on the other. And, above all, the housing problem is responsible for the conditions which foster prostitution. By more efficient inspection of houses throughout the country, and by local authorities undertaking the provision of new houses, it is hoped that a partial solution, at any rate, of this problem may be found; and in the meantime it is considered urgently necessary by Hr. Ribbing and his colleagues that the present legislation dealing with child welfare should be extended so as to give the authorities certain powers over young adults of 15 to 18. Compulsory education and detention of the incipient prostitute of this age would, it is urged, do much to convert the potential vagabond to an industrious and virtuous worker.

*Travelling Consultants for Venereal Clinics.*

Referring to a proposal made in this column on Sept. 6th (p. 451) to appoint travelling consultants for venereal clinics, “Fair Play” writes:—

“Your suggestion is excellent, but I should like to add that it does not go far enough, and that what is wanted is a complete overhaul of the present personnel. The majority of these clinics were started during the war, and appointments of medical officers were made from those available at the time. In some cases these appointments have been dealt with in the spirit of a closed corporation, and are reserved for members of the hospital concerned, irrespective of their knowledge of venereal disease. There are now many medical men demobilised who have had experience in Military V.D. Hospitals, to say nothing of pre-war experience, and who have returned to find the doors to these new appointments bolted and barred. As the Ministry of Health is spending public money on these clinics, it is ‘up to’ the Ministry to see that the money is spent to the best advantage, and that these appointments are made by a system of open competition. I have recently been consulted by a patient who has been woefully mistreated at one of these new clinics, owing apparently to ignorance on the part of the medical staff.”

## Correspondence.

"Audi alteram partem."

## CONTROL OF VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—The letter in your last issue under this title from Sir Bryan Donkin with regard to the deputation from the National Council for Combating Venereal Diseases to the Public Health Committee of the London County Council, hardly does justice either to the London County Council or the National Council. The London County Council has no "policy of passivity." I know that it is prepared to go as far as it possibly can in providing facilities for treatment of venereal disease; but it declines to assist in establishing centres for "early preventive treatment," holding that the establishment and public advertisement of such centres would be a direct incitement to vice. Administrative and financial difficulties also influenced it.

It is obvious from its answer to the deputation that the County Council did not then realise that the main request of the National Council was for greatly increased facilities for effectual and continuous treatment, and that the "preventive" side was an adjunct.

The policy of the National Council for Combating Venereal Diseases is simple—"Personal cleanliness directly after risk of infection, and prompt resort to a medical man." No question of "6 hours" arises with regard to it.

I am Sir, yours faithfully,

E. B. TURNER, F.R.C.S.,

Chairman of the Medical Committee, N.C.C.V.D.  
81, Avenue Chambers, Southampton-row, London, W.C.I.,  
Sept. 24th, 1919.

## THE BRITISH FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

To the Editor of THE LANCET.

SIR,—In your issue for Sept. 20th appears an attempt made by the officers of this body to reply to a corrected proof of my letter to you of Sept. 6th, headed "The Cult of Individualism," the receipt of which you acknowledge in your issue for Sept. 13th, but which, however, you have not seen your way to publish.

As you have deprived your readers of the benefit of seeing this letter and thus of forming an unbiased opinion with regard to the many points at issue, it is quite impossible to deal satisfactorily with the question when treated with such want of fair play. Your heading to the Correspondence column—"Audi alteram partem" would seem to support this contention.

I am, Sir, yours faithfully,

Have, Sept. 19th, 1919.

E. ROWLAND FOTHERGILL.

\*\* Before we were able to publish Major Fothergill's letter—and the delay was entirely due to his own wish—it appeared in the *British Medical Journal*. As the exact reference to this publication was given by Sir Malcolm Morris and his co-signatories, there could be no conceivable reason for using space in reprinting the letter. Major Fothergill knows perfectly well why his letter was not printed, so that his accusation of unfairness on our part is not a candid one.—ED. L.

## POST OFFICE CONTRACT PRACTICE.

To the Editor of THE LANCET.

SIR,—The principle of contract practice is that small annual payments should be made regularly by a number of patients during periods of health, the amount being calculated to cover the expense of attendance on those patients who incur illness. In the case of the Post Office, whose medical officers are paid on this system, the principle has, in my opinion, been entirely lost sight of and destroyed.

Early in the war when postal employees joined the Army, the Post Office medical officers were notified that each man's name, as he joined, would be removed for the time being from the doctor's capitation list, but that when the man returned, even if invalided, he would then be restored to the list. I protested vigorously at the time, pointing out that if the men were to be restored to the list, whatever their

state of health, on returning from military service, their capitation fee should continue to be paid during the interval of absence, especially as military service was likely to injure health in many ways. My protest was, of course, useless. Names were removed regularly from my list, with the result that my salary declined as follows: 1915, £16 16s. 9d.; 1916, £10 19s. 1½d.; 1917, £9 17s. 5d.; 1918, £9 0s. 9d.; and doubtless every other Post Office medical officer has experienced a like decline of salary.

The men are now returning, and I have just received a letter from the surveyor of the district apprising me of the restoration to my capitation list of a man invalided from the Army after months of illness from Mesopotamian malaria and who is only a fortnight out of hospital in England. His spleen is still palpable and he cannot walk a mile without breathlessness. He is now restored to my list for treatment at the rate of 8s. 4d. a year, although I have not received a penny for him for the last three or four years.

If these returning men are to be attended by us as before I maintain that at the very least their capitation fees for the period of their absence in the Army should be paid to us, and I have replied to this effect to the surveyor.

I am, Sir, yours faithfully,

Bromsgrove.

H. CAMERON KIDD.

## THE IRISH PUBLIC HEALTH COUNCIL.

To the Editor of THE LANCET.

SIR,—You announced last week in THE LANCET the names of the Irish Public Health Council, but without comment on them.

This Irish Public Health Council, whose duty is to advise the Chief Secretary, as Health Minister, as to what changes Ireland needs from a public health point of view, was indeed wrongly constituted at the outset. It is believed in Ireland that the situation has been largely due to the advice of the Irish Branch of the General Medical Council, where of seven members only one is elected by the whole profession. The Irish medical profession was never consulted as to the Public Health Council, on whom, however, the burden will fall of attempting to carry out any new health scheme. The Chief Secretary was early advised that the new Council was going to be wrongly constituted, that the medical members were too few in number, and that the profession as a whole should help in the selection of their own representatives. He knew our views even before the Bill went to the House of Lords, but he allowed himself to be guided by his permanent officials in Dublin. As a result he has—and it is his first attempt at a constructive measure in Ireland—as a Council to advise him as to the future public health measures necessary for the whole of Ireland, a body of 17 members, which has a medical representation which is too small and which is unrepresentative in knowledge of the general practice of this country, being wholly comprised of Dublin persons.

I am, Sir, yours faithfully,

Sept. 20th, 1919.

IRISH MEDICAL PRACTITIONER.

\*\* One of our Irish Correspondents deals with the matter this week.—ED. L.

DEATH OF SIR PETER WYATT SQUIRE.—The death of Sir Peter Wyatt Squire, which took place suddenly on Sept. 17th, removes a prominent and distinguished figure from the pharmaceutical world. His services to pharmacy, and to the Royal Household in his official capacity of pharmacist, were recognised by the King a little over a year ago, when His Majesty conferred upon him the honour of knighthood. His name will always be associated with "Squire's Companion to the Pharmacopœia," a valuable compilation initiated by his father, the late Peter Squire, who was President of the Pharmaceutical Society, 1861-63. Peter Squire's work laid the foundations of the British Pharmacopœia. Sir Peter Wyatt Squire devoted much time and attention to keeping the "Companion" up to date, and carried out considerable experimental work directed to verifying and revising the official tests. He did also some original work on methods of preparing tissues for microscopic work. His advice on pharmaceutical preparations and compounding was eagerly sought by the medical profession, and his prescience in regard to approved and valuable formulæ is well known.

## Obituary.

WILFRID OMBLER MEEK, M.B., B.S. LOND.,

MEDICAL SUPERINTENDENT OF BROMPTON HOSPITAL SANATORIUM, FRIMLEY.

Dr. W. O. Meek, whose joint contribution with Dr. J. J. Perkins and Dr. R. A. Young appears in our present issue, died in his sleep on Sept. 14th at the sanatorium which he so ably superintended. He received his medical education at St. Thomas's Hospital, London, where he held a Louis Jenner research scholarship, and after graduating in medicine at London University in 1905 he was first house physician and then assistant director of the clinical and pathological laboratories. A house appointment at the Brompton Hospital for Consumption turned his interests in that direction, and when Dr. Marcus Paterson left Frimley Sanatorium to direct the Welsh National Memorial it naturally fell on Dr. Meek to succeed him in the important post at Frimley. Of his work there a friend (J. J. P.), who was staying with him at the time of his death, writes:—

As the superintendent of a sanatorium for tuberculosis Meek was ideal, and if ever a man found his proper work in life it was he. He seemed to have all the gifts necessary for success in such a post and all departments of his work appealed to him equally. Nature and training had combined to fit him in this peculiar degree. His love of outdoor life and outdoor things gave him the interest in and grasp of the management of the estate and the patients' work which was so noticeable and made this side of his life an unflinching delight to him.

As a physician he started with a sound training in clinical work gained in resident posts to which his years as assistant in the clinical laboratory at St. Thomas's Hospital added a thorough insight into modern pathology and modern methods of research and their application to the problems of tuberculosis. In this he had the advantage over the ordinary physician. The writer has often admired the happy suggestions and explanations his scientific knowledge enabled him to give of puzzling clinical symptoms. Even after he went to Frimley, side by side with his administrative duties, he continued his research work, and in addition to what has been published he has left a large mass of valuable experimental results on which he was still at work.

Based on this thorough grasp of the pathology of tuberculosis, he had an equally thorough grasp of the principles of treatment, on which he held strong views. One can sum up his treatment by saying he was patient and wonderfully persistent and, it is not too much to say, profound. Add to these qualities a marked capacity for organisation and a firm, though sympathetic, character, and one need look no further for the secret of the respect and affection he won from all and of the contented, cheerful, though active, atmosphere one felt throughout the institution. Everything went like clockwork and went well.

It is almost unnecessary to add that he was quite unconscious of his many gifts, and day by day seemed just intent on the day's work being well done. Towards his friends he was thoughtful kindness itself and a very genial, hospitable companion. As one went about with him one realised after a time that he had a deep sense of sympathy with the patients, which made him leave nothing untried for their benefit. He was slow to give up hope for them, and everyone had a good chance to improve. He knew every case thoroughly, the details of their lives and work as well as of their illness.

In late years he had become much impressed with the necessity of making in many instances some alteration in their after-life at home to enable them to maintain their health. He gave a good deal of attention to this side of his work, with excellent results, entering into each case individually and giving really practical advice and help. It was from this point of view that he threw himself enthusiastically into the farm colony scheme of the National Association for the Prevention of Tuberculosis and gave almost daily supervision to the preparations for the colony which lies almost close to the Frimley Sanatorium. He had very large ideas and plans as to the instruction which could be given there. His death is a severe blow to every phase of tuberculosis work.

Dr. Meek's critical attitude of mind was well shown in his contribution to a discussion at the Medical Society of London on the Value and Limitations of Sanatorium Treatment as regards the Working Classes, a report of which appeared in THE LANCET of Nov. 24th, 1917. He carried out the principles of sanatorium treatment rationally and

scientifically, adapting them to the new developments of the times. It was his happy lot to find himself able to modify the prognosis in the case of his more resourceful and intelligent patients by attention to after-care. And where he showed the way others may follow.

## Medical News.

THE OPENING OF THE MEDICAL SCHOOLS.—At the opening of the October Session in the Metropolitan Medical Schools the following arrangements have been made:—

*St. Bartholomew's Hospital.*—The annual dinner will be held on Sept. 30th, at 7 for 7.30 P.M., at Princes Restaurant, Dr. W. S. A. Griffith presiding.

*Charing Cross Hospital.*—The annual Students' Dinner will be held at the Adelaide Gallery, Strand, on Oct. 1st, at 7.30 P.M., Colonel William Hunter presiding. The prizes will be distributed at the hospital on the same date by Sir Auckland Geddes, President of the Board of Trade.

*St. George's Hospital.*—The opening address will be delivered by Dr. Squire Sprigge, at 3 P.M., on Oct. 1st. The annual dinner will take place at Princes Restaurant, Piccadilly, on the same day, at 6.30 for 7 P.M., when the chair will be taken by Dr. J. H. P. Fraser, D.S.O., M.C.

*Guy's Hospital.*—The biennial dinner will take place at the Connaught Rooms, at 7 P.M., on Oct. 28th, Dr. Lauriston Shaw in the chair.

*King's College Hospital.*—The introductory address will be given by Dr. T. J. Macnamara, LL.D., on Oct. 1st, at 3 P.M. The annual dinner will be held on the same day at 7 P.M., at Pagani's Restaurant, Sir St. Clair Thomson presiding.

*London Hospital.*—Sir Bertrand Dawson will preside at the dinner of the Old Students, which will be held at Princes Restaurant on Oct. 2nd, at 7.30 for 8 P.M.

*St. Mary's Hospital.*—The prizes will be distributed on Oct. 1st, at 3 o'clock, by Lieutenant-General Sir John Goodwin, Director-General of the Army Medical Service. The annual dinner of Past and Present Students will be held on the same evening at the Connaught Rooms, Sir Almroth Wright in the chair.

*Middlesex Hospital.*—The introductory address will be delivered by Sir John Bland-Sutton, at 3 P.M., on Oct. 1st, and Surgeon Rear-Admiral Sir Robert Hill will distribute the prizes. The Annual Dinner will be held on Oct. 1st, at 6.30 for 7 o'clock, at the Holborn Restaurant, and the Earl of Athlone, chairman of the Hospital, will preside.

*St. Thomas's Hospital.*—The Old Students' Dinner will be held on Oct. 1st, at 7.30 P.M., in the Connaught Rooms, Great Queen-street, London, Sir George Makins, P.R.C.S., presiding.

*University College Hospital.*—The annual dinner of Old Students will be held at the Imperial Restaurant, Regent-street, on Oct. 3rd, at 7 for 7.30 P.M. Sir John Rose Bradford in the chair.

*Westminster Hospital.*—The annual dinner will be held on Oct. 2nd at the Imperial (Oddenino's) Restaurant, at 7 for 7.30 P.M. Mr. Walter George Spencer in the chair.

*London School of Medicine for Women.*—The introductory address will be given by Dr. Christopher Addison, Minister of Health, at 3 P.M., on Oct. 1st.

THE GRESHAM LECTURES.—On Oct. 14th, 15th, 16th, and 17th, at 6 P.M., Sir Robert Armstrong-Jones will deliver four lectures at Gresham College, Basinghall-street, London, E.C., on the Evolution of Military Medicine and Surgery from Ancient Times and the Medical Lessons Derived from the Great War. The lectures will be free to the public.

THE INCORPORATED SOCIETY OF TRAINED MASSEUSES.—The members' conference takes place in London from Oct. 2nd-4th. On Thursday, Oct. 2nd, at 11 A.M., Captain F. Wood Jones, R.A.M.C., lectures on "What We Know of Ourselves," at the Royal Society of Arts, 18, John-street, London, W.C.; at 2.30 P.M., Major R. C. Elmslie, R.A.M.C., deals with "Deformities of the Spine," at St. Bartholomew's Hospital, after which members are free to visit various departments of the hospital. On Friday, Oct. 3rd, at 11 A.M., Dr. Justina Wilson lectures on "Diseases of the Respiratory Tract," at the Royal Society of Arts; at 2.15 P.M., visits to various departments at St. Thomas's Hospital, by kind permission of the authorities; at 3.15 P.M., a demonstration of gymnastic work will be given by Miss Randell, sister-in-charge of the massage and exercises department of St. Thomas's Hospital; and at 6 P.M., a lecture will be delivered by Colonel A. H. Tubby on "Stiffness of Joints," at the Royal Society of Arts.

**THE RÖNTGEN SOCIETY.**—The officers and members of council for the ensuing year have been elected as follows:—President: Dr. Sidney Russ. (Past Presidents for last three years: Major C. Thurston Holland, Major G. W. C. Kaye, Dr. G. B. Batten.) Vice-Presidents: Mr. J. Hall Edwards, Professor A. W. Porter, Professor J. W. Nicholson. Honorary Secretaries: Dr. Robert Knox, Dr. R. W. A. Salmond. Honorary Treasurer: Mr. Geoffrey Pearce. Honorary Editor: Major G. W. C. Kaye. Council: Mr. W. E. Schall, Dr. G. H. Rodman, Dr. C. Howard Head, Mr. C. R. C. Lyster, Dr. J. Metcalfe, Dr. E. P. Cumberbatch, Dr. A. E. Barclay, Mr. F. J. Harlow, Dr. W. Makower, Dr. E. A. Owen, Dr. J. Russell Reynolds, Mr. R. S. Wright.

**BRITISH ORTHOPÆDIC ASSOCIATION.**—The annual meeting will be held at the rooms of the Medical Society of London, 11, Chandos-street, W., on Nov. 14th, when the President, Mr. Muirhead Little, will deliver an address. At 10.30 A.M. there will be a discussion on Kineplastic Amputations, in which Mr. T. H. Openshaw, Mr. S. Alwyn-Smith, Sir J. Lynn-Thomas, and Major M. Fitzmaurice-Kelly will take part, and in the afternoon a discussion on Birth Paralysis will be opened by Mr. H. A. T. Fairbank and Mr. Harry Platt. Mr. A. S. B. Bankart will discuss the Operative Treatment of Spastic Paralysis. The annual dinner will be held during the evening of the same day, and on Nov. 15th hospital demonstrations will be arranged, as well as a visit to the Country Hospital for Cripples at Pinner.

**DEATH OF MR. W. M. HOPE.**—Mr. William More Hope, M.R.C.S., L.S.A., D.P.H., medical officer of health for the city of Gloucester, was found dead in bed at his residence in Denmark-road last Monday morning. He had not been in good health for some little time, but discharged his official duties up to the last. He was 64 years of age, and took the diplomas of Member of the Royal College of Surgeons and Licentiate of the Society of Apothecaries in 1878, after which he was for over 10 years secretary and house surgeon to the Stamford and Rutland General Infirmary. While there his attention was directed more especially to preventive medicine and public health, and having passed the examinations of the Conjoint Board for the diploma in Public Health he went to Gloucester to practise in April, 1905, and was appointed medical officer of health of the city and port of Gloucester in succession to the late Dr. John Campbell. He was also appointed school medical officer to the city education committee under the medical inspection scheme. Dr. Hope was a bachelor.

**SOCIETY FOR THE STUDY OF INEBRIETY.**—An autumn conference of the Society for the Study of Inebriety will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Tuesday, Oct. 14th. The conference is open to all members and associates without fee, who may also introduce visitors on forwarding their names and addresses to the honorary secretary. The proceedings will include a breakfast, which will be held at the Polytechnic, 309, Regent-street, W., at 8.30 A.M., when the chairman of the National Temperance League, Mr. Robert Whyte, jun., will preside, supported by Sir Alfred Pearce Gould, Lord D'Abernon, Sir Thomas Whittaker, M.P., and Dr. Mary Scharlieb. Mr. Theodore Neild, chairman of the League's Science and Education Committee, will present an address. Those desiring to be present should communicate with Mr. John Turner Rae, secretary, at the offices of the League, 34, Paternoster-row, E.C.4. The sessions of the conference will be held in the Hall of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. At the morning session, at 10.30, the President of the Society, Sir Alfred Pearce Gould, will deliver an introductory address, after which Lord D'Abernon will open a discussion on "The Scientific Basis of Drink Control." At the afternoon session, at 2 P.M., Sir Thomas Whittaker will open a discussion on "Alcohol in Relation to Recreation and Refreshment and the Public House." Special papers will be presented and discussed at the morning and afternoon sessions, and among communications promised are the following: "Alcohol and Alcoholism in Relation to Venereal Disease," by Mr. Arthur Evans; "Analytical Psychology in Alcoholism," by Dr. Maurice Nicoll; "Special Clinics for Inebriates," by Dr. J. A. Davidson; "The Influence of Dilution on the Toxic Action of Alcoholic Liquids," by Dr. H. M. Vernon. Tea will be served in the Library to members and associates attending the conference at 4.30 P.M. At 5.30 the eighth Norman Kerr Memorial Lecture will be delivered by Dr. Mary Scharlieb, C.B.E., M.D., M.S., in The Robert Barnes Hall of the House of the Royal Society of Medicine, 1, Wimpole-street, the subject being "The Relation of Alcohol and Alcoholism to Maternity and Child Welfare."

## The Services.

### ROYAL NAVAL MEDICAL SERVICE.

Surg. Rear-Admiral H. W. G. Doyne is placed on the Retired List at own request.  
Surg.-Capt. G. A. Dreaper is promoted to Surgeon Rear-Admiral.

### ARMY MEDICAL SERVICE.

Col. C. A. Young, C.B., C.M.G., retires on retired pay.  
Col. G. T. Rawnsley, C.B., C.M.G., is placed on the Half-pay List under the provisions of Article 351, Royal Warrant, for pay and promotion.  
Cols. A. J. Luther, C.B., H. L. Knaggs, C.B., C.M.G., and B. H. Scott, C.M.G., retire on retired pay.  
Temp. Col. C. J. Symonds, C.B. (Major, R.A.M.C., T.F.), relinquishes his temporary commission on re-posting.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. E. McDonnell relinquishes the temporary rank of Colonel on re-posting.

The undermentioned relinquish the acting rank of Lieutenant-Colonel: Major O. L. Otway, Capt. R. G. S. Gregg, Temp. Capt. G. W. Milne.

Major and Bt. Lieut.-Cols. G. Ormrod and A. W. Samper relinquish the acting rank of Lieutenant-Colonel.

Major H. F. Shea relinquishes the acting rank of Colonel on re-posting.

R. H. Nicholson, Fleet Surgeon, R.N., ret., to be temporary Major.

Capt. J. D. Roche relinquishes the acting rank of Lieutenant-Colonel on ceasing to command a Medical Unit.

Major T. B. Moriarty to be acting Lieutenant-Colonel whilst specially employed.

Capt. J. J. Molyneux and R. G. S. Gregg to be acting Majors whilst specially employed.

The undermentioned relinquish the acting rank of Major: Capt. J. Biggam, A. L. Foster, T. L. Fraser; Temp. Capt. E. McCulloch, A. C. Hancock, J. C. D. Allan, E. S. Sowerby, C. Y. Ford (on ceasing to be specially employed).

Temp. Capt. (acting Major) R. H. Lucas to be Captain, and to retain his acting rank whilst specially employed.

Capt. J. C. Sproule to be acting Major.

The undermentioned temporary Captains to be acting Majors: J. M. Macfie, H. G. Hobson, and J. Graham and E. K. Campbell (whilst specially employed).

Late temporary Captains to be temporary Captains: P. Kitchen, G. L. Neil, R. W. D. Hewson, W. B. Honey, G. B. Proctor.

To be temporary Captains: J. A. Jardine and F. J. R. Cowie.

Officers relinquishing their commissions:—Temporary Lieutenant-Colonels retaining the rank of Lieutenant-Colonel: J. V. G. B. Tighe, W. Harding, M. A. Collins. Temp. Majors H. T. Jenkins, G. D. Gray (granted the rank of Lieutenant-Colonel), R. T. Smith (retains the rank of Major), Temp. Capt. (Bt. Major) W. E. P. Phillips (retains the brevet rank of Major). Temp. Capt. G. Robertson.

Temporary Captains granted the rank of Major: A. G. Anderson, R. W. P. Jackson, A. W. G. Woodforde, E. F. G. Ward, A. K. Cosgrave, C. D. Faulkner, R. J. B. Madden, R. S. Barker, A. Dick, G. Muir, E. Tawse, A. E. Quine, J. Donald, W. J. Johnson, R. S. Miller.

Temporary Captains retaining the rank of Captain: G. N. Kirkwood, E. H. Stone, R. L. Sinclair, A. L. McGarry, J. Dulberg, D. W. Smith, B. C. Ewens, J. J. Armistead, J. E. Barnes, L. H. Skene, A. Cleland, F. G. Gibbs, J. P. P. Inglis, R. H. Maingot, J. R. Davies, R. M. Lang, L. Cohen, L. Gray, J. Allan, M. Culpin, R. H. Fleming, J. C. Padwick, A. W. T. Whitworth, A. F. Wright, R. W. Telford, A. R. Wightman, A. B. Cooke, F. J. Whitelaw, J. H. Fryer, B. B. Noble, R. T. Grant, W. F. O'Regan, S. Rodin, C. F. Dillon-Kelly, A. Graydon, J. T. Titterton, H. P. Shackleton, G. Riddoch, D. Young, C. B. Tudehope, J. B. Fisher, A. D. Blakely, W. Simpson, C. H. L. Rixon, E. Gofton, J. W. N. Hohhouse, G. F. May, A. E. Hardy, C. Gordon, T. J. Lydon, H. O. West, W. H. Trethowan, H. Spurway, A. Robertson, R. G. McQueen, C. Salkeld, P. L. L. Craig, A. B. Lindsay, P. Ashe, F. O. Siedman, E. M. Condy, F. Penny, W. P. Miles. Temp. Hon. Capt. J. M. Bremner (retains the honorary rank of Captain). Temporary Lieutenants retaining the rank of Lieutenant: H. T. O'Neill, S. F. Breakey, A. I. Girdwood.

### Canadian Army Medical Corps.

Temp. Major J. A. Lussier and Temp. Capt. E. E. Locke retire in the British Isles.

M.B.E.—Surg.-Cmdrs. G. E. Duncan, A. Gaskell, C.B., and H. W. Gordon-Green, R.N.; and Surg.-Lieut. A. G. L. Reade, R.N.V.R.

In a despatch describing events in Syria and Palestine, subsequent to the conclusion of the armistice with Turkey on Oct. 31st, 1918, received from Field-Marshal Sir E. Allenby, Commander-in-Chief of the Egyptian Expeditionary Force, the following reference to the Medical Services appears:—

The Medical Services have dealt successfully with the difficulties of evacuation over long distances in a country of undeveloped communications; and have combated with excellent results the chief scourge of Syria and Palestine—malaria. I desire to mention the good work of Major-General A. E. C. Keble and Major-General Sir R. H. Luce, as Directors of Medical Services at various periods.

### THE AERIAL COMBATANT:\*

HIS PSYCHOLOGY AND NERVOUS PHYSIOLOGY CONSIDERED IN THE LIGHT OF ATHLETIC ANALOGIES.

BY THE LATE H. G. F. SPURRELL, M.A.,  
M.B., B.CH. OXF.,  
CAPTAIN, R.A.M.C.

#### PART I.

WHEN early in the war it was recognised that a powerful aerial army was required, the training of a large number of men began. It was suspected that the number of men who proved disappointing under training could be reduced if a scientific method of selection could be evolved. This expectation has been to a great extent justified; but failures under training still occur, and a very large proportion of these failures can be traced to nervous and psychological causes. This may be partly due to the practical difficulty of detecting nervous weakness when selecting a flying officer, but his duties make such unusual demands upon his nervous system that chance may easily subject even the soundest material to a breaking strain. Much has yet to be learned regarding the selection of the right nervous organism, how to train it when selected, and how to estimate its recuperative powers when damaged. In the light of some small experience gained on the selection and invaliding boards of the Royal Air Force, and in no less instructive daily intercourse with members of a great school of military aeronautics, I have attempted to sketch out the nervous physiology of training for aerial combat, and to trace to underlying physiological bases some of the factors which make for success or failure in the flying combatant. Such an attempt may be profitable, though the risk must be faced of saying much that is already tediously obvious.

#### *Training of the Flying Fighter.*

A flying fighter must undergo three distinct stages in his education. Firstly, he must be taught to fly. He must learn to fly instinctively with no more conscious mental effort in handling his machine than a cavalryman of the old school exerted in keeping his seat and managing his horse. Secondly, he must learn to fight, to drop his bombs with calculation and precision, but making many of the incidental movements subconsciously, and to manipulate his machine-gun with a trained hand but a free mind. Thirdly, having learned both to fly and to fight in the air, he must learn to use military intelligence. He must be able to watch what is going on in a *mêlée*, decide quickly whether to single out an opponent or go to the help of a friend, to use judgment when bombing in choosing objectives, and he requires special knowledge for gaining, interpreting, and using information which may come in his way. The old-time trooper with a firm seat and a fine wrist was a long way from being the complete cavalryman, and the skilful aeronaut who is dextrous with weapons has yet to become a flying soldier. With all this to learn the tyro's nerve centres need extensive and progressive development, and it may clarify one's ideas to translate the process into physiological terms.

Learning to fly may be compared with learning any other motor accomplishment. The required movements have to be worked out in consciousness by the highest cerebral mechanism. The muscles which are to perform them have to be developed to the strength requisite for acting harmoniously in the new combinations. When the movements have become clear conceptions which can be consciously carried out by trained muscles, these conceptions have to be passed down the scale of nervous controlling centres until they become the property of reflex centres and can be performed automatically, not merely without requiring thought, but without interrupting thought. Learning to fly is closely analogous to learning to bicycle: the stages of the nervous education are the same. It is also analogous to learning to walk, but here the analogy cannot be pressed so far. Evolution has not, either by structural adaptation or by nervous tendencies, given man an hereditary predisposition to fly analogous to the predisposition to walk. In flying and in bicycling the brain acts consciously by selecting, inhibiting, and adapting the established reflexes to new purposes; but the process is not shortened by any of those instincts which urge a child, in whom intelligence is only

dawning, to make persistent efforts to walk when its mother thinks it would still be much better employed crawling.

Man's capacity for education is, however, conditioned by his evolutionary history. While most animals have specialised for a particular place in nature, in man we see an animal capable, by means of tools and education, of specialising himself for many diverse requirements. One of his most recent attempts at self-education is for the air. He has not the exclusive specialisation for flight which evolution has produced in the bat, so if he is to fly he must attain his end by devising mechanical means and training his nervous system, and this he has proved himself capable of doing. But, together with the intelligence and versatility which enable him to elaborate movements, man must have a very complete power of delegating the controls elaborated by his brain to lower automatic centres. Only so can he prevent his brain from becoming overloaded and keep it free to deal with present needs. Only so, moreover, can he shorten his reaction times and so gain the necessary rapidity for meeting the emergencies of daily life.

#### *The Education of the Nervous System.*

In actually learning to fly one may trace three distinct stages in the education of the nervous system. First there comes the cerebral stage. The way in which the machinery of the aeroplane works is constantly before the mind and the muscular movements to produce the right effects in it have to be thought out and performed consciously, with mental effort. Errors become slighter as time goes on, because adaptations are taking place in the receptive side of the nervous system, which is learning to deal with a multitude of unfamiliar afferent stimuli. The first stage passes gradually into the second, or the stage of transition. During this stage automatic action is becoming perfected and conscious direction more and more restricted. The pupil learns, by flying with an instructor in a machine, under what is known as "dual control." Now the relations of the instructor to his pupil are very closely parallel to the relation of the higher centres of the brain to the automatic centres lower down the scale in the central nervous system. The progressive education of the pupil and the reflex centres, and the continually lessening intervention on the part of the instructor and cerebral cortex present no very strained analogy. But during the stage of transition there is a period when the aeroplane, though described officially as under dual control, is, physiologically speaking, under treble control. The nervous system of the instructor works harmoniously and may be regarded as a unit; but the pupil, whose conscious and automatic nervous centres have not yet arrived at a satisfactory division of labour, is more accurately to be described as two individuals than one. The conscious and subconscious nervous centres competing for the control of the muscles resemble a fussy, over-anxious instructor continually trying to help a wayward and awkward pupil. From what instructors tell me I gather that this is the least safe period in the pupil's career, and one can well understand that between the three controls the machine may come to the ground.

With the arrival of the third stage flying becomes instinctive. The pupil thinks of what he will do, not how he will do it, and he learns by observation and experiment how all manner of various conditions affect his doing what he wants to do. Even now, of course, the pupil is not immune from mishap. The venturesome type may come to grief by attempting things which are beyond his powers or the structural capacity of his machine; the careless type may have an accident because he "lets his wits go wool-gathering." The weakness of this type lies in a deficient power of inhibition. It cannot repress irrelevant stimuli which interfere with the essential action. Both these types prove unsafe flyers in spite of a successful education, but they are essentially deviations from the normal. In the normal man the most dangerous source of accident is a mental disturbance in which the cerebral hemispheres endeavour once again to take charge of actions which have for some time past been performed automatically.

The extreme difficulty of attempting and the disastrous results which often follow an attempt to perform consciously actions which have become reflex are matters of common knowledge, and it is only when we attempt to perform actions with especial care that we learn how many are really automatic. We have all seen the well-educated man, who can speak fluently in ordinary life, splutter, become incoherent, and break down when called upon to make a speech or to interview someone of importance. This is because he is making conscious efforts to speak clearly and grammatically, and we have all seen him recover miraculously when the impudence of a heckler distracts his attention from the cares of elocution, or the urbanity of a great man "sets him at his ease" by diverting his mind in the direction of the subject of his interview. When a pilot can fly by established reflexes which only need general orders from the presiding intelligence it is very perilous for the volitional centres to attempt suddenly to resume control. They can

\* This paper was received by us after the author's death. Reference to the obituary notice in THE LANCET of Jan. 4th (p. 42) will show the high qualifications which Captain Spurrell brought to his task.

resume control cautiously and deliberately in efforts to improve by practice movements which are not yet perfect, but that is another thing. Self-consciousness is the disturbing element. For instance, a man unused to flying in Egypt knows that the shimmering sand and blinding glare will make the conditions of his landing unlike those of grass in a grey light, and he may easily worry about this, and as he approaches the ground allow his conscious volition to hamper his reflexes with disastrous results. On the other hand, a man suddenly perceiving an obstacle when on the point of landing, will make the complex movements necessary to avoid it quite subconsciously and automatically. Whether he comes off safely depends on extraneous circumstances. In himself he has every chance.

This return of conscious control after reflex control has been established is like an old instructor, long retired from flying, going up with one who was formerly his pupil, but is fully proficient and in much better trim than himself. If the older man nervously insists on flying in dual control and in interfering whenever a difficulty confronts them the pair will probably crash. If the veteran is there solely as a passenger to use his experience for strategic purposes and occasionally offer advice on major tactics they will probably do excellent work. When the pilot's nervous system has been so trained that the reflex mechanism can carry out the requirements of intelligent volition, yet the higher centres which act consciously can be relied on never to embarrass the highly educated reflexes by untimely interference, then the third stage in his education is completed and he can be said to have learned how to fly.

#### THE METROPOLITAN WATER-SUPPLY DURING APRIL, MAY, AND JUNE, 1919.

On the whole, the month of April this year maintained its tradition in regard to rain, and, in fact, the rainfall in the Thames basin was 2.76 inches, being 1.02 inches above the average mean rainfall for that month during the previous 36 years. The Thames water was at times more or less coloured and turbid. Nevertheless, the results of the chemical examination showed that, generally speaking, all three raw waters (Thames, New River, and Lee) showed an improvement in quality as indicated by the albuminoid nitrogen, permanganate, turbidity, and colour tests. The filtered waters also showed an improved chemical quality compared with the previous month, and the samples collected at the different works were clear and bright and free from suspended matter. The results compared favourably also with the averages of the previous year. Bacteriologically the Thames and New River raw waters contained fewer and the River Lee raw water more bacteria than their respective averages for 1918. The filtered waters were satisfactory from this point of view. May was a dry month, the rainfall being 0.64 of an inch, being 1.34 inches below the average mean rainfall for this month during the previous 36 years. The Thames and New River raw waters showed a deterioration in quality by chemical tests. The raw waters of the Thames and Lee contained fewer and the New River more bacteria than their respective averages in 1918. The filtered waters were again satisfactory. June was also a relatively dry month, with the rainfall standing at 1.06 inches, being 1.13 inches below the average mean rainfall for that month during the previous 36 years. All three raw river waters showed, generally speaking, improved quality judged by chemical and physical tests. All three proved to contain fewer bacteria than their respective averages for the year 1918. There were no typical *B. coli* in 100 c.c.m. of the water in 72.4 per cent. of the filtered samples derived from the Thames, 36.8 per cent. from the Lee, and 77.9 per cent. from the New River. Judged on this high standard the Lee filtered water was inferior to the others. It is interesting to note that the April report is stamped "Local Government Board," while those for May and June are marked "Ministry of Health."

#### THE MISCEGENATION OF SHAKESPEARE.

To the physical anthropologist miscegenation must mainly be of interest as it affects human anatomy. As the school of Professor Keith points out, the races of the British Isles are "much of a muchness" from the point of view of craniology—they are practically all dolichocephalic; where long-headed races become intermixed that school does not regard the resultant types as it would half-breeds or mulattos. In more historic times than those of physical anthropology the question of miscegenation becomes important from the point of view of brain-differentiation and culture-drift. For the long heads are not all alike either in mental heredity or civilisation.

Shakespeare is the fine flower of English genius. That "Shakespeare" was a pseudonym, chosen by Bacon to express the fact that the Author of the Plays brandished the spear of Pallas in the great age of Elizabeth is a suggestion combated by the history of surnames. Shakespeare, a common name in Warwickshire, is Shalk's Byre, "the farm of the villen," who, in that part of

England, was descended from a Romanised Briton. That Shakespeare, the man, was a very pronounced instance of miscegenation is an attractive supposition. His genius has been described as both Teutonic, or Northern—i.e., Anglo-Saxon—and as British, Celtic, or rather Cymric, for he combines virility with mystery in a degree unknown to the German Goethe on the one hand or the old Welsh bards on the other. We may grant, at least, that Shakespeare was a combination of Saxon and Briton, and that this is reflected in his masterpieces. What, however, were the ancient Britons, from whom the shalks of the hyre descended? According to the late Sir Jonathan Hutchinson, who bases himself on Dr. Baynes, the Shakespeares, as well as Mary Arden, the poet's mother, came of Roman stock. In a very acute short paper, published in "The Home University" (October, 1898) Sir Jonathan Hutchinson points out a number of considerations in favour of this position. "During the Roman occupation," he says, quoting Baynes, "Warwickshire was the site of several central Roman stations, of which the fortified camps of Tripontium and Prædium, on the line of the Avon, were the most important. A Roman road crossed the Avon at Stratford, and radiating north and south, soon reached some of the larger Roman towns of the west, such as Uriconium and Corinnum. Between these towns were country villas or mansions, many of them being, like those at Woodchester, magnificent palaces covering as much ground as a whole town. The entire district must in this way have been powerfully affected by the higher forms of social life and material splendour which the wealthier provincials had introduced." Nay, more, according to Coote ("Romans of Britain," published in 1878), the whole of Britain, but especially the West, remained essentially Roman to a late date, the country having been everywhere measured out and allotted by *agrimensores* to scions of good Roman stocks (Julii, Cornelli, &c.), whose descendants founded our western squirearchy in preference to the rude Saxon invaders of the fifth and succeeding centuries. Is it too extravagant to suppose that through the Arden family, at any rate, Shakespeare derived the fissures of his brain and the aquiline cast of his features? The Iberian or Mediterranean type lingers everywhere in rural western England. Often it startles us by its Roman nobility of contour. Who has not come upon a face suggestive of Julius Caesar in the lonely fields along the remote Upper Thames at Bampton or in any remote region of Wessex?

Sir Jonathan Hutchinson closes his article with the remark: "Of Shakespeare's symmetrical and noble face we will only say that it is not one which could be easily matched in Denmark, and still less so in Germany. The resemblance of George Eliot's face to that of Savonarola has often been remarked, and as regards character a close parallel might be drawn between Savonarola and Fox." George Fox, a man of profound and original spiritual genius, was born at Fenny Drayton, George Eliot (Miss Evans—a Welsh name) at Nuneaton, Samuel Butler, author of "Hudibras," in the same neighbourhood, the Shakespeares were a Snitterfield stock, the Ardens came from the Forest of that name. These places were within 15 miles of Coventry. They represent a pocket of exceptional genius, due to a mixture of culture-drifts and the survival of a higher mental type. A similar pocket has been discovered by Professor Keith in the countryside of the Hunters, which produced in its day a remarkable group of medical men of genius.

#### EDUCATED HOME HELPS FOR THE MIDDLE CLASSES.

THE attention of practitioners is called to a newly established bureau for the provision of educated middle-aged women, experienced in housekeeping and holding certificates in first aid, home nursing, and invalid cookery, to help in private homes in cases of illness. No actual nursing will be undertaken, but such work as looking after the house and children, invalid's food, shopping, and mending. It is anticipated that the scheme will be doubly useful to women of slender means who desire part-time employment, and, on the other hand, to professional women living alone in a flat attended by a charwoman only, or to mothers with large households whose convalescence is too often retarded by worry about the servants, the shopping, and the children's meals. In the modern servantless middle-class homes, where at most the services of a daily maid are available, an illness of the mistress which confines her to bed is likely enough to bring household affairs to a full stop, as well as to create a period of added strain to the invalid. We take it that the new help is intended to replace the former ubiquitous unmarried sister or sister-in-law, who is nowadays usually a busy bachelor woman and seldom available in emergency. The payment will be not less than 10d. an hour or 5s. a day with food, or 25s. a week with all meals. All applications for educated home helps or from suitable candidates for employment should be made to the Women's Industrial Council, 6, York Buildings, Adelphi, W.C.2.

## DISEASES OF THE EYE

New (8th)  
Edition

By G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology, University of Pennsylvania. Octavo of 754 pages, with 386 illustrations and 7 coloured plates.

Cloth, 30s. net.

*"Its outstanding merit is the abundant reference to all the most valuable contributions to the literature of the subject in recent years, and Dr. de Schweinitz succeeds in incorporating these details without marring the general perspective—no easy task. .... We can cordially recommend the book as belonging to the small group of the very best text-books on ophthalmology."*

—THE LANCET.

Sixth  
Edition

## GENERAL BACTERIOLOGY

Recently  
Issued

By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago. Octavo of 691 pages, illustrated.

Cloth, 18s. net.

*"The lucidity and systematic arrangement make it very suitable as a general introduction to bacteriology, and the more so since the subject is treated as part of a general scientific education and not merely as part of the technical instruction of the medical student, though it will serve his purpose."*—THE LANCET.

New (2nd)  
Edition

## BLOOD-PRESSURE

Recently  
Issued

By FRANCIS A. FAUGHT, M.D., formerly Instructor in Medicine at the Medico-Chirurgical College at Philadelphia. Octavo of 478 pages, illustrated. Cloth, 18s. net.

*"The immense value of such a survey to anyone about to undertake a study of blood-pressure is easily realised, and the book will appeal to all who are interested in this difficult and complicated subject."*—BRITISH MEDICAL JOURNAL.

New (2nd)  
Edition

## MATERIA MEDICA

Recently  
Issued

PHARMACOLOGY, THERAPEUTICS, and PRESCRIPTION WRITING.

By W. A. BASTEDO, Ph.G., M.D., Associate in Clinical Medicine at Columbia University, New York. Octavo of 654 pages.

Cloth, 20s. net.

*"Dr. Bastedo's book is pleasantly written, well illustrated, and carefully arranged. It may be confidently recommended to all who desire to improve and bring up to date their information on the important subject of treatment."*—BRITISH MEDICAL JOURNAL.

New (3rd)  
Edition

## CHEMICAL PATHOLOGY

Revised and  
Enlarged

By H. GIDEON WELLS, Ph.D., M.D., Professor of Pathology, University of Chicago. Octavo of 707 pages.

Cloth, 19s. net.

*"We feel sure that this work will not only provide a great storehouse of garnered knowledge on a difficult yet fascinating subject, but will serve to stimulate research as well as to guide treatment."*—THE LANCET.

Second  
Edition

## BACTERIOLOGICAL TECHNIQUE

Second  
Edition

By J. W. H. KYRE, M.D., Bacteriologist to Guy's Hospital, London. Octavo of 518 pages, illustrated.

Cloth, 13s. net.

*"The book is stamped throughout with evidence that the writer is a practical teacher, and the directions are more clearly given than in any previous work."*—THE LANCET.

Superb  
Illustrations

## PATHOLOGIC HISTOLOGY

A Standard  
Work

By FRANK B. MALLORY, M.D., Associate Professor of Pathology at Harvard Medical School. Octavo of 677 pages, 497 figures (683 original illustrations), 124 in colours.

Cloth, 25s. net.

*"We urgently recommend it to all students of pathology."*—DUBLIN JOURNAL OF MEDICAL SCIENCE.

SYSTEMATIC AND PRACTICAL, INCLUDING EMBRYOLOGY. In One Volume.

FOURTH EDITION. Revised by a Committee of Demonstrators in Anatomy.

q "The special point about this book is that it claims to be the only English text-book of anatomy retaining the old nomenclature, which is still official, and speaking generally, seems to be much preferred by students as being more simple and quite correct enough for all practical purposes. A large number of terms of the Basle nomenclature is given for reference, however, in an appendix."—LANCET.

Pp. xii. + 1743. With 677 Illustrations, mostly Original and in Colours. PRICE 30s. net.

(Almost Ready)

## Dictionary of Treatment

q "One of the qualities of a practical work like this is to tell what to do in emergencies, and with this dictionary handy for reference one is sure never to be caught napping."—MEDICAL PRESS AND CIRCULAR.

Enlarged to Demy 8vo.

Pp. x. + 1080.

PRICE 25s. net.

BAILLIÈRE, TINDALL &amp; COX, 8, Henrietta Street, Covent Garden, London, W.C. 2.

## Repairs by New Process

Damaged Surgical Gloves may be restored as good as new by the new process for which BATES have sole rights in the U.K.

Slits or tears are mended and new fingers or wrists fitted so neatly by the process that the surgeon cannot feel the mends. Repeated sterilisation does not affect them; the cost is trifling.

Used regularly by many General and Naval and Military Hospitals.

Write for fuller particulars and prices to—

Customers unable to visit can rely on having a perfect fit guaranteed by sending an old suit as a guide for size.

## Better than Cure

IF only the public more widely realised the service of Wolsey's Pure Wool in preventing many of those ills which threaten us so constantly in this incorrigible climate it would be "all to the good" for everyone.

Medical Men and Nurses may commend Wolsey Underwear with full confidence not only in its hygienic excellence and economic value, but also in the assurance that it will definitely assist in the encouragement and maintenance of health.

Wolsey's record will endorse this.

# WOLSEY

THE BEST THE WORLD PRODUCES

There are Wolsey garments in great variety for men, women, and children, and every garment carries the well-known Wolsey guarantee against shrinkage in wash or wear. Any failure in this respect means a new garment free.

All good Hosiery, Drapers, Outfitters, and Sorens can supply Wolsey, and the Wolsey Head trade mark proves its genuineness.

# BELDAM

## All-British Tyres

**For Long Mileage & No Skids**

**T**HE narrow tread of the Beldam All-Rubber de Luxe (see illustration) assures speed and resiliency. The "V" shaped projections at either side of the tread effectively prevent skidding. They also serve to brush to one side such puncture makers as nails, flints, &c., instead of turning them up (as the tyres of round tread are apt to do) for the back wheels to pick up.

Booklet "Testimony" gives the opinions of users of Beldam Tyres on their wearing and non-skidding qualities. May we send you a copy?

## The Starting and Lighting System of your Post War Car.

**EVERY** Motorist will demand perfection and efficiency in every detail of his post-war car. He will want a Starting and Lighting System of undeniably good qualities, and in the **Smith Starting and Lighting System** he will find everything he requires.

The Smith System is paramount among electrical apparatus for motor-cars, combining a powerful, positive, automatic starter device, worked conjointly with a proved never-failing lighting system. An unusually high standard of efficiency and serviceability is embodied in the Smith System because of the many distinct and improved features it possesses.

The Smith Starting and Lighting System worthily upholds the great reputation of the greatest Motor Accessories House in the world, and will form an integral part of the equipment of the most of the post-war cars.

Write to-day to Messrs. S. SMITH & SONS (M.A.), Ltd., 179-185, Gt. Portland St., London, W.1, for a copy of their little booklet, "A New Era in Motoring," which describes in detail the Smith Starting and Lighting System.

Mr. S. F. EDGE writes in "THE MOTOR":—

"During this winter I have been running with a set of Duco Spring Gaiters supplied by Brown Brothers, Ltd., and it is perfectly amazing how such a simple device does add to the comfort of a car. The springs work quite differently when kept under first-class lubrication conditions. .... I am quite sure it will not be long before the springs will be as perfectly lubricated and sufficiently protected from dirt and water, as the gears in the gear box are, and any manufacturer who turns out a car with all the leaves of the springs open to the weather will be looked upon as just as foolish as would be the case if he had no gear box round his gears."

## Metatarsalgia and Callouses Caused by Weakened Anterior Arch

This condition is recognised by depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is described by Whitman as Morton's Toe. These conditions are quickly relieved and permanently corrected by the use of

### Scholl's Corrective Foot Appliances.

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. Different types to meet all emergencies.

Sold and fitted by leading shoe dealers in every community, who have been instructed in Anatomy of the foot and how to properly apply correctives to the foot and shoe.

*SCHOLL'S APPLIANCES can be of great value to the medical man in prescribing for Foot Ailments. May we send you descriptive circular?*

### *Extract from the Report to the Local Government Board on Dried Milks*

*(Food Reports No. 24).*

"In his report for 1911, Dr. Robinson speaks especially of the good results during the diarrhoea epidemic in September of that year. Of 240 babies under one year fed on Glaxo, only 1 died; of 160 others, 37 died. In the report for 1915, it was stated that almost without exception infants correctly fed on Glaxo thrive and are up to the normal standard. In a recent communication Dr. Robinson informs me that they now distribute 30,000 lbs. yearly of dried milk at no cost to the ratepayers. He considers its excellence as a food proved beyond all doubt." (Page 69.)

# PHENOQUIN

(Southall)

is specific in the elimination of uric acid from the system. It is the one British product replacing the pre-War German Atophan.

Phenoquin has proved exceptionally efficacious in acute Gout, chronic Gout, and other forms of Arthritis, promptly causing a remarkably rapid increase in uric acid excretion.

Phenoquin has also proved its value in acute articular Rheumatism and Sciatica. Dosage—5-15 tablets daily. Descriptive circular for Medical men; post free on application.

Packed in bottles of 50 and 100 tablets. Price 6/- & 11/-

*Composition: Lactose & Formaldehyde*

## ALDEMINT

*Registered*

### Antiseptic Throat Tablets

Effectively replace treatment by 'gargles' in relaxed throats and laryngeal ailments generally.

Invaluable both as a prophylactic against Influenza, Diphtheria, Tonsillitis, etc., and for public speakers, actors, etc.

In bottles containing 50 tablets  
 2/-, of all Chemists.

(LYSOL BRITISH)

## LYCRESOL

### A Standardised Disinfectant

A well tried antiseptic in concentrated form for the use of doctors and nurses. It contains a high percentage of cresol, and is superior as a general disinfectant and deodoriser to carbolic acid.

As Lycresol forms a saponaceous solution it easily removes mucous secretions, etc., with adherent germs.

A Measuring Cup with each bottle.

Price:—4 oz. 9d.; 8 oz. 1/3; 16 oz. 2/3; 32 oz. 3/6;  
 1 gall. tins 14/-

*A powerful urinary antiseptic.*

## Cystoformin

*Trade Mark*

Its range of usefulness is very wide, embracing practically every infected condition of the bladder or urinary tract.

Composition:—Hexamine with Sodium Acetate representing 40 per cent. of its weight of the former. In 17 gr. tablets. Taken dissolved in water.

Sold in Tubes containing about 20 tablets, 16 each.

## Vitafer

**The All-British Tonic Food**

*Awarded Gold Medal at the last International Congress of Medicine.*

VITAFER, introduced before the outbreak of war, now holds the foremost place amongst tonic foods.

It is distinguished in containing the entire protein of milk, (Lactalbumen and Casein) in being the richest in assimilable phosphorus and in being non-constipating.

A doctor's sample will be sent free and post paid to any Medical Practitioner on request.

In sealed tins, price 2/- & 3/- of all Chemists;  
 larger sizes 5/6 & 10/-

# HIPPURATES

OF

## SODIUM, AMMONIUM and LITHIUM,

indicated in cases of hypertension and in arterial pressure, and as a preventative treatment in Gout and Arterio Sclerosis.

IN POWDER AND TABLETS.

Prices and particulars on application.

Est'd 1820

**Southall Bros. & Barclay Ltd. Birmingham**

Prescribed by the Medical Profession for 35 years.

*The LANCET (London, Eng.) describes it as—"Mr. Benger's admirable preparation."*

## BENGER'S FOOD.

### "Cause and Effect" explained.

**B**ENGER'S FOOD is a cereal flour free from indigestible and irritant particles and scientifically combined with natural digestive principles, which cause it to become, after preparation, one of the most easily assimilated and highly nutritive foods extant, and one which leaves very little insoluble or irritant residue.

The digestive process is easily and simply regulated by allowing the food to stand, after the mixing with warm milk, for 5 to 45 minutes.

The effect is that the casein in the milk, which otherwise would form tough indigestible casein curd in the stomach, can only separate into minute flocculae; in addition both the protein and carbohydrate material in the food itself are partially converted, so as to be easily assimilated by weakened digestive systems.

*This explains why Benger's is frequently retained when all other foods are rejected—why it can be taken by the most delicate infant, and by persons prostrate with illness.*

## Benger's Food

for INFANTS, INVALIDS AND THE AGED,  
is sold throughout the World by Chemists, &c., in sealed tins.

*Full particulars will be sent post free to Members of the Medical Profession  
on application to Sole Manufacturers:*

BENGER'S FOOD Ltd., ——— Otter Works, MANCHESTER, Eng.

Canadian Agents—National Drug & Chemical Co., Ltd., 34, St. Gabriel Street, MONTREAL and  
depôts throughout Canada.

N.B.—BENGER'S FOOD is the direct outcome of the pioneer work on digestive ferments, by the late Sir William Roberts, M.D., F.R.S., and the late Mr. F. Baden Benger F.I.C. F.C.S. in 1880, since when it has been the premier dietetic preparation of its kind in the British Empire.

# OVALTINE

TONIC FOOD BEVERAGE

## DIET IN DISEASE

**I**N acute disease, where the digestive functions are impaired and excessive nitrogenous metabolism necessitate easily assimilated nourishment, "OVALTINE" will be found of great value.

"OVALTINE" is composed of a highly concentrated extract of the vitalizing and building-up properties contained in Malt, Milk, and Eggs, and presents the essential elements of diet in well-balanced proportions. It forms a natural anabiotic for administration in debilitated conditions where tissue waste has to be restored with a minimum of digestive strain.

*Supplied by all Pharmacists.  
Special low prices are quoted to  
Hospitals and Kindred Institutions  
on direct application to the makers.*

A liberal trial supply will be sent to members of the Medical Profession in private or hospital practice.

## ALL REACTIONS <sup>of the</sup> Body Fluids & Tissues are COLLOIDAL.

COLLOSOLS are pure and stable collioidal solutions, isotonic and isomorphic with the elements of the body.

CROOKES'

# COLLOSOLS

COLLOSOLS are tested by ultramicroscopic bacteriological and clinical experiment.

## COLLOSOL SULPHUR.

This Collosol is of proved therapeutic value in Fibrositis, Arthritis Deformans, Neuritis, and in diseases of the skin such as Generalised Dermatitis, Acute Psoriasis, Acne and Seborrhœa.

Collosol Sulphur is not presented as a substitute for the Spa treatment of such affections where Spa treatment is available, but as a supplement to it. A course of treatment at a Spa can be followed up by the exhibition of Collosol should relapses occur.

For patients who are unable to take a course of Spa treatment, practitioners will find Collosol Sulphur invaluable.

It is prepared in five different forms—for external use and bath medication, for internal administration, for injection, and as a cream, with which the affected part is gently massaged. Also as an oil for the scalp.

For evidence of the therapeutic efficacy of Collosol Sulphur, the medical profession is referred to the Second Report of a Committee of the British Association for the Advancement of Science, recently published on behalf of the Department of Scientific and Industrial Research, pp. 168-9.

## COLLOSOL MANGANESE

for the treatment of Boils, Carbuncles, and other Coccic Infections. Also for the treatment of Anæmia (see *British Medical Journal*, August 2nd, 1919, pp. 135-6).

## COLLOSOL ARGENTUM.

This Collosol has an extensive field of usefulness as a general non-toxic antiseptic, and, unlike the salts of silver, it causes no pain or discoloration.

For testimony to its great efficacy in gonorrhœal ophthalmia—See *British Medical Journal*, April 5th, 1919, pp. 404-5.

## COLLOSOL IODINE.

This Collosol consists of Iodine in its most active form, and yet non-toxic and non-staining. It never causes nausea and never sets up iodism.

For its efficacy in parasitic affections—See *British Medical Journal*, May 12th, 1917, p. 617.

IN TUBERCULOSIS

# "BYNOL"

To maintain body weight  
and generally to promote  
nutrition in Incipient  
Phthisis & Wasting Disease

"Bynol" is a combination of Cod-Liver Oil and Malt Extract, having exceptional nutritive power. The Oil used in its manufacture is a pure product, in the preparation of which Messrs. Allen & Hanburys have been directly engaged for over half a century at Lofoten and Søndmør, Norway. Medical reports show that it is one of the best weapons for arresting loss of weight and increasing capacity for assimilation.

# "Polyglandin"

*Indicated in Hysteria & Uterine Disorders. Also in Neurasthenia, Melancholia & Sexual Neuroses*

TREATMENT by pluriglandular extracts favours general secretory activity, and many cases of apparently monoglandular deficiency benefit more by mixed hormone treatment than by the administration of the extract from a single isolated unit of the endocrinous gland system. It is now recognised that normal metabolism depends upon the hormone balance being maintained, and that the functions of the endocrinic organs are plural rather than singular. The administration of gland substances must not be regarded from the narrow standpoint of replacing a deficient secretion, but rather as stimulating particular organs to greater activity for a longer or shorter time. "Polyglandin" enhances muscular, mental and nervous activity, and is a general stimulant to the cardio-vascular system.

CONTAINS THE  
ACTIVE PRINCIPLES  
OF THE THYROID,  
PARATHYROID,  
OVARY, TESTIS &

# Glykeron and Glyco-Heroin

ARE SYNONYMOUS APPELLATIONS AND ARE NOW KNOWN AS SUCH TO ALL DISPENSING PHARMACISTS

**T**HESE designations may now be used interchangeably by the physician when prescribing the preparation originally known only as Glyco-Heroin (Smith).

As a safeguard against having worthless imitations of the preparation dispensed, it is suggested that the physician use the name

## GLYKERON

which is non-descriptive and more distinctive, when prescribing GLYCO-HEROIN (SMITH) for **Cough, Asthma, Phthisis, Pneumonia, Bronchitis, Laryngitis, Whooping-Cough, and kindred affections of the respiratory system.**

DOSE—The adult dose is one teaspoonful every two hours or at longer intervals as the individual case requires.

For children of ten years or more, the dose is from one-quarter to one-half teaspoonful; for children of three years or more, five to ten drops.

---

The composition of GLYCO-HEROIN (SMITH) has not been modified in the slightest degree.

# "MALTINE"

"MALTINE" PLAIN should not be confounded with ordinary so-called malt extracts.

"Maltine" differs from ordinary preparations of malt in that:—

- (1) "Maltine" contains the concentrated nutritive elements and organic phosphates of the choicest malted grain.
- (2) "Maltine" is absolutely pure and free from preservatives.
- (3) "Maltine" is standardised in Diastase, so that one part of "MALTINE" converts ten parts of starch into sugar at the body temperature.
- (4) "Maltine" is more economical. Only one half of the ordinary dose need be prescribed in the case of "MALTINE."

The chief indications of "Maltine" are:—

- (1) "Maltine" is a powerful starch digestant, and is very successful in cases of ptalytic and pancreatic insufficiency, and all conditions showing amylaceous indigestion.
  - (2) "Maltine" is a reconstructive nutrient of proved merit.
  - (3) "Maltine" is a good supplementary nutrient for nursing mothers. It invariably improves the character of the milk and maintains an adequate flow.
  - (4) "Maltine" forms an ideal vehicle and emulsifying agent for cod liver oil, cascara, creosote, hypophosphites, phosphates, iron, and pepsin.
  - (5) "Maltine" is now largely used in fever dietary as a supplement to milk.
  - (6) "Maltine" when added to milk prevents coarse curdling, and is now generally used in invalid and infant feeding for that purpose.
- It is also a preventive of constipation in infants fed on cow's milk.

In prescribing, kindly specify "MALTINE COMPANY."

*Specimens and Literature sent Free of Charge to Medical Men on request.*

**THE MALTINE MANUFACTURING COMPANY, Limited,**  
183, ACTON VALE, LONDON, W. 3.

A dainty and attractive form  
of tonic - food medication.

# SANATOGEN CHOCOLATE

(Genuine Sanatogen skilfully mixed with Pascall's pure Chocolate.)

It is now generally admitted that pure chocolate is a most nourishing fat food and a delightful stimulant—particularly valuable for growing children, who need relatively more sugar than adults; for invalids whose palates require tempting; and for those who dislike eating fat or have difficulty in digesting starchy foods.

Its nutritive and sustaining properties—so much appreciated during the war by soldiers subject to extreme fatigue and exposure—are greatly reinforced by the addition of the well-known tonic-food Sanatogen which, being an exceptionally fine powder with no strong taste or odour, does not render the chocolate “muddy” or unpalatable.

Sanatogen Chocolate must not, however, be regarded as therapeutically equivalent to Sanatogen, since the former cannot be administered in sufficiently large doses to produce the same effect as the latter; but the presence of this tonic-food does undoubtedly increase the dietetic value of the chocolate.

*SANATOGEN CHOCOLATE is obtainable of all Chemists.*

### SURRENDER OF THE CITY OF PTOLEMAIS, OR ACRE, TO THE CRUSADERS

Every country of Europe had poured forth its soldiers to take part in the siege of Acre which had already lasted twenty-two months when Richard Cœur de Lion and Philippe-Auguste of France reached the Holy Land to meet the armies of Saladin. Together they carried on the siege. At length, after nearly three years, during which armies had been almost annihilated and then reconstructed with fresh recruits, the Saracens were reduced, by famine, pestilence and exhaustion to the necessity of the surrender. In the scene here reproduced from a French painting, the besieged are laying down their arms and delivering up the keys of the city to the kings surrounded by their armies. The terms agreed to were that the true cross should be given up to the allies, 1000 men and 200 knights in captivity were to be surrendered, the sum of 200,000 pieces of gold was to be paid within forty days, failing which the inhabitants of the city were to be considered at the mercy of the conquerors. The English and French armies were then instructed not to harm any who should leave the city. On entering Acre each nation represented took possession of one of the quarters. Under one pretext or another Saladin delayed, and did not carry out the terms. Richard, irritated, massacred 5000 Moslems—an act which was regretted by his whole army. Date, A.D. 1191.

# CHELTINE MILK AND MALTED FOOD

No. 1. From earliest Infancy to 5 months.

No. 2. From 5 months onwards.

Regarding these **CHELTINE FOODS**, a well-known dietetic authority writes:—

**"They contain all the elements necessary for a complete Food for Infants. Being a Malted Food, it may be given in early infancy without producing constipation. It is beautifully prepared, so as to be readily assimilable by the digestive organs."**

The great importance of the choice of Food for the growing, healthy Infant is fully appreciated by the Manufacturers of Cheltine Milk and Malted Food, its composition being based on the physical and physiological requirements of infant life. Experience has proved, and medical men have testified to, the value of this Food, used as directed, in the rearing of healthy babies. It is a safe and reliable tissue-builder, manufactured by food-specialists of long standing.

*Packed in air-tight tins in three sizes:—6½ oz. 1/7½; 13 oz. 3/-; 26 oz. 5/9.*

**No. 3 CHELTINE MILK & MALTED FOOD** for **INVALIDS, DYSPEPTICS, the aged, and those with enfeebled digestions**, prices as above, is being increasingly prescribed by the Medical Profession.

*Should any difficulty be experienced in obtaining these Foods locally, please write, giving name and address of usual Chemist or Store, to the Manufacturers—*

# MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps, the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power MIST. DAMIANÆ CO. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

*Dose—One or Two Drachms in Water.*

## MEDICAL OPINIONS.

"I have tried your Mist. Damianæ Co. considerably in the dyspepsia of commencing phthisis, and can very strongly recommend its use in those cases. It soothes the stomach wonderfully, and enables the patient to take more food whilst acting as a powerful stimulant in relieving exhaustion."—Yours faithfully, W. H. B—, B.A. (Cantab.), M.R.C.S., L.S.A.

**THE MEDICAL ANNUAL.**—"Damiana is not used so frequently in this country as in America, where its value as a tonic for Neurasthenia is well known. Messrs. HEWLETT & SON put up a very excellent preparation of this drug, combined with Nux Vomica and simple aromatics and bitters, which is valuable for dispensing, and yields very satisfactory results in treatment."—1898.

Dr. M—, R.N., writes:—

"Farnham (Hants.), Sept. 1903.

"I have frequently prescribed your Mist. Damianæ Co. and proved it efficient in treating Neurasthenia."

**Packed in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.**

Introduced and Prepared only by—

**C. J. HEWLETT & SON, LTD., 35 to 42, Charlotte St., LONDON, E.C.**

**It was impossible during the war to obtain  
full supplies of**

# HORLICK'S MALTED MILK

because of the demands of our fighting men on Land, Sea, and in the Air, and thousands of letters testify to their appreciation of its value. Supplied extensively to the War Office, Admiralty, R.A.F., Indian Soldiers' Fund, Prisoners of War, and many Red Cross Organisations.

## INTRAMINE

A non-toxic organic amino compound of sulphur which is injected in the form of a colloidal emulsion in the treatment of

### SYPHILIS, PROTOZOAL and CHRONIC BACTERIAL DISEASES and ACID INTOXICATIONS (Metallic Poisoning, &c.)

In syphilis and protozoal diseases 'INTRAMINE' is used as an alternative to pave the way for the administration of the metallic drugs, and to prevent intoxication following their use.

Among chronic bacterial diseases, 'INTRAMINE' is most efficacious in gonorrhœal rheumatism, urethritis, acne rosacea and seborrhœic eczema.

In metallic poisoning, such as mercurial stomatitis, and arsenical dermatitis, 'INTRAMINE' is of great value, also in jaundice and albuminuria.

'INTRAMINE' for intramuscular injection is supplied in two solutions which must be mixed immediately before use.

'INTRAMINE' for intravenous injection is supplied ready for use in 50 c.c. AMPOULES.

'INTRAMINE' for internal administration is supplied in KERATINISED GELATINE CAPSULES.

The King.

## BABY'S DIGESTION

It is not what is *eaten* that nourishes, but what is digested. "Condensed milk," says a medical authority, "is almost as digestible as peptonised milk." And a Hospital Secretary writes: "We often find that a baby can digest Nestlé's Milk when no other form suits it."

This explains what a Scottish mother recently wrote:—

"During my first little boy's illness the doctor ordered him to be put on a certain food, which I did for seven weeks, to my great sorrow, with the result—a hopeless case! But having heard of Nestlé's Milk I decided to try it, and in three days the baby was smiling at the doctor. He was so amazed at the remarkable improvement that he asked me what had done it, so I told him of Nestlé's Milk, and he named him 'the little wonder,' and said he was very proud of him. He is now two years and seven months old, and has never ailed one single day since Nestlé's introduced itself. My two children are really a credit to your milk, and I cannot speak too highly of the way they have thriven."

# THE BURBERRY

**The Super-Weatherproof**

**R**EPRESENTS the most economical and distinguished form of protection in out-door Dress.

**THE BURBERRY**, by its efficient resistance to rain and cold winds, ensures comfort and security under conditions entailing prolonged exposure to chill and damp.

**THE BURBERRY**, by faultless natural ventilation, entirely avoids the vitiated heat of macintosh or rubber-lined coats.

**THE BURBERRY** is airy and gives a splendid sense of freedom, whilst its hygienic warmth in chilly weather proves invaluable for maintaining health and comfort.

Patterns, Prices, and Catalogue sent on application.

## **BURBERRYS' CLEANING WORKS.**

Men's and Women's Dress Cleaned by the most up-to-date processes. Weatherproof garments reproofed. Moderate charges. Prices sent on request.

**BURBERRYS' BASINGSTOKE HOUSE** treats direct commissions from Doctors as approval orders—i.e., replaces with its own cheque returned non-approved garment.

FREDERICK WOOD, Secretary.

## Brompton Hospital Sanatorium,

Frimley.—The Committee of Management of the Hospital for Consumption and Diseases of the Chest, Brompton, S.W., invite applications for the post of MEDICAL SUPERINTENDENT at the Sanatorium. Salary £600 per annum, with board and residence. Candidates must be qualified to practise medicine and surgery and be duly registered. Applications, with testimonials, to be sent in not later than Thursday, 16th October, 1919. Further particulars may be obtained upon application to the Secretary at the Hospital.

Brompton, September, 1919.

FREDERICK WOOD, Secretary.

## St. Marylebone Infirmary.—Wanted

shortly, an ASSISTANT MEDICAL OFFICER (Male), whose main duties would be concerned with Tuberculosis. The Ward consists of some 90 beds (average occupied about 70-80), and are under the medical supervision of Dr. Halliday Sutherland, Visiting Physician to the Tuberculosis Wards.

The cases include every phase of Tuberculosis, and the appointment provides a wide experience which would qualify for other posts in the Tuberculosis Service. Salary £200 a year, all found. Garden. Quiet quarters. Good off-duty time. Apply, Medical Superintendent, St. Marylebone Infirmary, Rackham-street, Ladbroke-grove, W. 10.

## St. Marylebone General Dispensary,

77, Welbeck-street, Cavendish-square, W. 1.—A vacancy having occurred in the office of RESIDENT MEDICAL OFFICER to this Institution, the Directors are prepared to receive applications for the vacant office. Candidates must be registered, and hold a Medical and Surgical qualification. Salary £150 per annum, with furnished apartments, attendance, coals, and light. The appointment is for one year, the occupant being eligible to become a candidate for re-election on the vacancy being advertised. Written applications and testimonials to be forwarded not later than Monday, October 6th, and candidates must attend the Medical Committee at the Dispensary on Wednesday, 8th October, at 4.30 P.M. precisely. This appointment is suitable for a gentleman reading for a higher examination.

22nd September, 1919.

HUGH STOKES, Secretary.

**Royal Free Hospital, Gray's Inn-road,**  
W.C.1.—Applications are invited for the post of HONORARY ANÆSTHETIST. Information with regard to the times of duty may be obtained from the Secretary, to whom applications should be addressed on or before October 4th, 1919.

**Royal Free Hospital, Gray's Inn-road,**  
W.C.1.—Applications are invited from duly qualified and registered Practitioners for the post of CASUALTY OFFICER. Salary £100 per annum, with residence. Duties to commence on the 1st November, 1919. Applications, stating age, with three copies of recent testimonials, should be sent to the Secretary on or before October 4th, 1919.

REGINALD R. GARRATT, Secretary.

**Royal Free Hospital, Gray's Inn-road,**  
W.C.1.—Applications are invited for the post of SURGICAL REGISTRAR. Duties to commence on the 1st November, 1919. Candidates, who must be fully qualified, must apply, stating age, qualifications, and experience, accompanied by copies of three testimonials and addressed to the Secretary, on or before October 4th, 1919.

REGINALD R. GARRATT, Secretary.

**The Anti-Vivisection Hospital, the**  
BATTERSEA GENERAL HOSPITAL (Incorporated), Battersea Park, S.W.11.—RESIDENT MEDICAL OFFICER wanted for Cancer Wing, to work under Honorary Specialist's supervision. Some knowledge of Electro-Therapy essential. Commencing salary £200, with board, lodging, laundry, &c. Apply by letter, with copies of three recent testimonials, to Secretary.

**The Mothers' Hospital,**  
153-163, Lower Clapton-road, E. 5.  
A RESIDENT MEDICAL OFFICER is required at this Maternity Hospital and School of Midwifery. Commissioner Adelaide Cox, The Salvation Army Women's Social Work Headquarters, 280, Mare-street, Hackney, E. 8, desires to meet with a Christian woman for this important sphere of useful service.

**Manor House Orthopædic Hospital.**  
The Committee of Management require a RESIDENT SURGICAL OFFICER at £500 per annum, with board. The position carries the duties of Surgical Registrar, the seeing of out-patients and admission of new cases. Applications must reach the Secretary on or before 17th October. BERNARD GILBERT, Secretary, Manor House Orthopædic Hospital, North End-road, Hampstead, N.W. 3.

**Paddington Green Children's**  
HOSPITAL, London, W. 2.  
HOUSE PHYSICIAN. HOUSE SURGEON.  
These appointments will become vacant on 1st November, 1919. Salary of House Physician £150, and House Surgeon £150 a year, with board, residence, and washing.  
Applications, with copies of three testimonials, must be sent in to the undersigned not later than the 9th October.  
24th September, 1919. F. STANLEY CHEER, Secretary.

**The London Lock Hospital and**  
RESCUE HOME,  
283, Harrow-road, W. 9, and 91, Dean-street, W. 1.  
HON. SURGEON TO OUT-PATIENTS.

The election, which is by ballot of the Governors, will be duly announced to the candidates. No personal canvassing of the Board or Medical Staff permitted. Candidates must be Fellows of the Royal College of Surgeons (Eng.)  
By order of the Board.  
Sept. 23th, 1919. H. J. EASON, Secretary.

**County of London.—Appointment of**  
CORONER for the South-Eastern District of the County of London.—The London County Council invites applications from duly qualified persons for the appointment of Coroner for the South-Eastern District of the County of London. The salary attached to the office is £1186 4s. a year.

The Coroner will be required to provide the necessary office accommodation and clerical assistance, and also to defray all other expenses of the office (including the services of an approved deputy), except the actual disbursements under the Council's schedule of fees, allowances, and disbursements made at the holding of an inquest.

The duties of Coroners are regulated by the Coroners Act, 1887, and other Acts. Section 12 of the Coroners Act, 1887, provides that "Every Coroner for a county shall be a fit person, having land in fee sufficient in the same county whereof he may answer to all manner of people."

Preference will be given to persons who have served or attempted to serve with the Forces of the Crown.

Candidates must possess either a legal or a medical qualification, and the candidate appointed will be required to give an undertaking that he will devote his whole time to the duties of his office, and that he will agree to any future scheme that may be formulated by the Council affecting the salaries and duties of coroners.

Applications must be made on the official form which can be obtained from the Clerk of the London County Council, County Hall, Spring Gardens, S.W. 1. The latest time for receiving applications is 11 A.M. on Monday, 6th October, 1919.

Candidates must be British subjects, and it is desirable that they should not be under thirty-five or over fifty years of age.

Canvassing of members of the Council, either directly or indirectly, will be held to be a disqualification for the appointment.

JAMES BIRD, Clerk of the London County Council.

**St. Bartholomew's Hospital.—**  
ASSISTANT ADMINISTRATOR OF ANÆSTHETICS (non-resident).—The Committee invite applications for the above office. Candidates must be registered Practitioners. Applications, with testimonials, must be left with the undersigned, from whom further particulars may be obtained, on or before Monday, the 6th October, 1919.  
September, 1919. THOMAS HAYES, Clerk to the Governors.

**Queen Mary's Hospital for the East**  
END, Stratford, E. 15.—Applications are invited for the post of HOUSE SURGEON at the above Institution. Salary at the rate of £150 per annum, with board, apartments, and washing. The work of the Hospital includes Eye, Ear, Nose and Throat, and Maternity Departments.  
Applications to be sent at once to the undersigned.  
A. W. SCRIVENER, Secretary.

**The Prince of Wales's General Hos-**  
PITAL, Tottenham, N. 15.—Applications are invited for the following posts, vacant on the 15th October next:—  
HOUSE PHYSICIAN. £200 per annum.  
HOUSE SURGEON. £200 per annum.  
JUNIOR HOUSE SURGEON. £120 per annum.  
JUNIOR HOUSE PHYSICIAN. £120 per annum,  
with residence, board, and laundry.

The appointments are from 15th October to 15th April, 1920. Candidates (Male) must be duly qualified and registered, and applications, together with copies of three recent testimonials, to be sent to me on or before the 30th September next.  
September 16th, 1919. FREDK. W. DREWETT, Director.

**Bethlem Royal Hospital.—In con-**  
nexion with the above, another Hospital has been established (quite apart from the main building) at 52, Lambeth-road, S.E. 1, for the treatment of early cases of neurological and psychiatric interest. Applications are invited for the post of HONORARY NEUROLOGIST. Candidates must be duly registered Practitioners and either Graduates of a University or Fellows or Members of the College of Physicians. Further particulars in regard to the appointment, if desired, will be furnished by the undersigned, to whom applications, accompanied by copies of testimonials, must be forwarded on or before Monday, October 6th.  
JOHN L. WORSFOLD, Clerk.  
Bridewell Royal Hospital, New Bridge-street, E.C. 4.

**Bethlem Royal Hospital, Lambeth-**  
road, S.E. — Wanted, JUNIOR ASSISTANT PHYSICIAN. Candidates for this office must be fully qualified Medical Practitioners, possessed both of Medical and Surgical qualifications as required for registration by the General Council of Medical Education, provided they be either Members of a British College of Physicians or Graduates in Medicine of a British University recognised by the aforesaid Council, unmarried, and not exceeding thirty years of age.

The salary will be £350 per annum, with annual increments of £30, subject to the approval of the Court, to £500 per annum, apartments in the hospital, complete board, and laundry being provided.

All applications and testimonials must be accompanied by answers to a printed form, which with a copy of the duties may be obtained at my office here, and such applications, &c., must be forwarded to me on or before October 6th. Candidates are required to present themselves before the Medical Committee at Bethlem Hospital on Wednesday, October 8th, at 2.15 P.M.

JOHN L. WORSFOLD, Clerk.

Personal canvassing not allowed.  
Bridewell Royal Hospital, New Bridge-street, E.C. 4.

**The Hospital for Sick Children,**  
Great Ormond-street, W.C.1.—A RESIDENT MEDICAL SUPERINTENDENT is required on the 13th October, 1919.

Candidates are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, the 6th October, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for one year, but may be held subject to re-election for a period of three years. Salary £200 per annum, with board and residence in the Hospital, and £5 washing allowance.

Candidates must be registered Medical Practitioners, and must have held a responsible Hospital appointment.

All candidates must appear before the Joint Committees at their meeting on Wednesday, 8th October, at 5 P.M. precisely.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By order of the Committee of Management.  
September, 1919. JAMES MCKAY, Acting Secretary.

**The Hospital for Sick Children,**  
Great Ormond-street, W.C.1.—The following Resident appointments will shortly be vacant:—  
ASSISTANT CASUALTY MEDICAL OFFICER, 13th October, 1919.  
HOUSE SURGEON, 1st November, 1919.  
HOUSE PHYSICIAN, 1st November, 1919.

Candidates are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, 6th October, 1919, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointment is made for six months. Salary £50, washing allowance £2 10s., and board and residence in the Hospital. Candidates must be unmarried and possess a legal qualification to practise.

All candidates must appear before the Joint Committees at their meeting on Wednesday, 8th October, at 5 P.M. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By order of the Committee of Management.  
September, 1919. JAMES MCKAY, Acting Secretary.

HOUSE SURGEON wanted. The Hospital contains 125 surgical  
beds. There are in addition a Resident House Physician, Assistant  
House Surgeon, and two Casualty House Surgeons. Candidates must  
be fully qualified, registered, and unmarried, and preference will be  
given to such as have previously held a similar appointment. The  
salary is £200 per annum, with board and furnished apartments. The  
selected candidate will be required to enter into an agreement to remain  
not less than one year and to give or receive three months' notice to  
terminate his engagement. Applications, stating age, qualifications,  
and previous experience, with copies of testimonials, to be sent  
addressed "Chairman, House Committee."

BENJAMIN BROOKS, Secretary.

**The Gloucestershire Royal Infirmary**  
and EYE INSTITUTION.—There is a vacancy for an ASSISTANT  
SURGEON on the acting Medical Staff of this Institution.

By the rules of the Hospital "the Assistant Surgeon shall be a Fellow  
or Member of the Royal College of Surgeons of England, or a Fellow or  
Licentiate of the Royal Colleges of Surgeons of Ireland or Edinburgh,  
or a Graduate in Surgery of one of the Universities recognised by the  
Medical Council of the United Kingdom."

Candidates should send in their applications, diplomas, and testi-  
monials, under cover to the Secretary, on or before Wednesday, the  
29th day of October next.

Members of the acting Medical Staff are appointed by the Election  
Committee.  
Gloucester, September 25th, 1919. G. HURFORD, Secretary.

**City of Sheffield**—Wanted, Assistant  
TUBERCULOSIS OFFICER, to live at Winter Street Tuber-  
culosis Hospital, and to devote his whole time to the Municipal Tuber-  
culosis Scheme.

Salary £300 per annum, rising to £400 per annum by annual  
increments of £50, with board, residence, and laundry.

Applications, stating age, qualifications, and experience, with copies  
of testimonials, to be sent on or before October 8th, to the Medical  
Officer of Health, Town Hall, Sheffield.

**City of Sheffield.**—Education Com-  
MITTEE.—Appointment of SCHOOL DENTAL SURGEONS.—  
Applications are invited from duly qualified Dental Surgeons for  
appointment as School Dental Surgeons to the Education Committee.  
Salary to commence at £400 per annum, rising to £450 by annual  
increments of £25, with opportunity of increasing the amount by  
evening work at the Clinic.

The persons appointed will be required to devote the whole of their  
time to the services of the Committee, and to act under the super-  
intendence of the Chief School Medical Officer.

Forms of application may be obtained from the Secretary, to whom  
they should be returned not later than 13th October, 1919.

Personal canvassing will disqualify.

PERCIVAL SHARP, Director of Education.  
123, Hawley-street, Sheffield, 22nd September, 1919.

**Royal Berkshire Hospital.**—The  
Board of Management invite applications for the appointment  
of HONORARY ASSISTANT PHYSICIAN.

Candidates must be Fellows or Members of the Royal College of  
Physicians, London, or Medical Graduates of one of the Universities of  
Great Britain or Ireland, and must be registered.

The elected candidate will be appointed for the period ending on the  
third Tuesday in January, 1920, but will be eligible for re-election.

Candidates are required to provide 65 copies of their application, and  
of not more than four recent testimonials.

The applications and testimonials must be addressed to the Secretary,  
and reach him not later than October 11th, 1919.

The election will take place on October 21st, 1919.

Canvassing by or on behalf of the candidate will disqualify him.  
Reading, 27th September, 1919. HERMAN BURNBY, Secretary

**Surrey Lunatic Asylums Visiting**

COMMITTEE, Brookwood, near Woking.—Appointment of  
FIRST ASSISTANT MEDICAL OFFICER.—Applications are invited  
for the post of First Assistant Medical Officer under the Surrey County  
Asylums Committee from duly registered Medical Practitioners who  
have had previous experience in Asylum work.

Salary, if married man is appointed, £600 per annum, rising by  
annual increments of £25 to a maximum of £700 per annum, together  
with a house free of rent, rates and taxes; if a single man, £480, rising  
by annual increments of £25 to £580, with board, lodging, attendance,  
and laundry.

The appointment will be subject to the rules and regulations affecting  
the Asylum and will be determinable by three months' notice on  
either side.

Applications upon the prescribed form, which can be obtained from  
the undersigned, may be accompanied by copies of not more than three  
recent testimonials (which will not be returned), must be sent not later  
than the 8th October, 1919.

R. A. HODGES, Clerk to the Committee.  
County Hall, Kingston-on-Thames, 22nd September, 1919.

**Borough of Sutton Coldfield.**—

Applications are invited for the appointment of MEDICAL  
OFFICER OF HEALTH and SCHOOL MEDICAL OFFICER.

Area of Borough ... .. 13,030 acres.  
Estimated Population ... .. 22,000.  
Rateable Value ... .. £143,565.

Schools—10 in number. School population about 2,400.

An office is provided in the Council House in connexion with the  
work of the Medical Officer of Health, to be used jointly by him and  
the Sanitary Inspector.

Office accommodation will also be provided at the Children's Welfare  
Centre in Holland-street, where the work of the School Medical  
Service, Infants Welfare, Dental Clinic, &c., will be carried on.

It is distinctly understood that the office of Medical Officer of Health  
and School Medical Officer will be a first charge on the time of the  
person appointed. He will be responsible for the organisation and  
supervision of the work of both services (including Infant Welfare, &c.),  
and have control of the Sanitary Inspector and his assistants, and the  
School Nurses and Health Visitors, with a view to the proper coordina-  
tion of these services, to be carried out so as to comply with the  
Statutes and the Regulations of the Government Departments con-  
cerned. He will attend and report to appropriate Committees of the  
Council, and prepare such Statistics, Reports, &c., as may be required  
by them or the various Government Departments. Salary according to  
experience and qualifications.

Applications, with copies of three recent testimonials, to be addressed  
on or before the 18th October, 1919, to  
Sutton Coldfield. R. A. REAY NADIN, Town Clerk.

**Manchester Royal Infirmary.—**

Sydney House, 26, Cockspur-street, London, S.W. 1,  
8th September, 1919.

**The Secretary of State for the Colonies**

announces vacancies for pensionable posts of **MEDICAL OFFICERS** in the Occupied Territory of **GERMAN EAST AFRICA.**

The salary is on the scale of £400-£20-£500 a year, with duty allowance of £40 a year, and after six years' service £525-£25-£600 a year, with duty allowance of £50. War bonus is granted at present at the rate of £55 per annum to unmarried officers and £105 per annum to married officers.

The Senior appointments in the Medical Department are those of Senior Medical Officer on the scale of £600-£25-£750, with duty allowance of £60, and of Deputy Principal Medical Officer, Senior Sanitary Officer, and Principal Medical Officer, the scales for which are not yet determined.

Particulars as to leave and pension may be had on application. Free quarters are provided or an allowance is given in lieu, and free first-class passages to and from East Africa are provided on first appointment and on leave.

Medical Officers are permitted to take private practice on the understanding that they give precedence to their official duties.

Intending candidates should write to the Private Secretary for Appointments, Colonial Office, Downing-street, S.W. 1.

No testimonials, &c., should be sent in until the candidate has received a form of application from the Colonial Office.

Downing-street, Sept. 9th, 1919.

## Alcresta Tablets of Ipecac in Amebic Dysentery and in Endamebic Pyorrhea

The oral administration of the ipecac alkaloids is proving more advantageous than the hypodermatic injection of emetine, especially in the treatment of endamebic carriers and in the prevention of relapses.

### UNCOATED AND DISINTEGRATING—CAUSE NO NAUSEA

Each tablet contains the alkaloids (emetine and cephaeline) from ten grains of Ipecac, U. S. P., held in an adsorption compound with hydrated aluminum silicate. The tablets disintegrate but this adsorption compound passes through the acid contents of the stomach and releases the alkaloids only in the alkaline intestinal secretions—thus preventing gastric disturbances.

*Ten or twenty tablets, representing one hundred or two hundred grains of ipecac, may be given in a day without vomiting or nausea.*

Distributed through the Drug and Dental Trades in bottles containing 40 and 500 tablets. Further information on request.

## **Valentine's Meat-Juice**

For Quieting the Irritable Stomach in Pregnancy, for Rapidly Restoring the Vital Forces in Hemorrhage, for Sustaining and Strengthening in Long and Exhausting Labor, Valentine's Meat-Juice is Extensively employed in

### Obstetrical Practice

**Dr. M. DeCristoforis, Prof. Lecturer on Midwifery and Gynecology, Milan, Italy:** "The preparation, VALENTINE'S MEAT-JUICE, has been successfully used by me in a serious case of acute puerperal hemorrhage. The patient could take no food or drink. VALENTINE'S MEAT-JUICE was completely retained and restored very promptly the strength and the cardiac impulsion."

**Dr. E. Dulooy, Physician Accoucheur to the International Hospital, Paris, France:** "A young accouchée, in a very weak condition and suffering from stomach trouble, could retain no food, but was able to assimilate VALENTINE'S MEAT-JUICE given at first in small doses. An improvement was quickly visible, the patient recovered her strength and is today in good health."

For Sale by European and American Chemists and Druggists.

*Mental Bankruptcy*

and nervous insolvency are the results of the present day tendency to go through life constantly on "high gear"

Brain, nerves, and body cells in general, need what have been called "chemical foods," such as calcium, sodium, potassium, phosphorus, manganese, and iron. The effect of these is favored by the "dynamic" action of small doses of quinine and strychnine, continued for a considerable period.

**Syr. Hypophosphites Comp. Fellows**

presenting these important elements in a uniform, stable, and easily assimilable form, is clinically efficient, as over fifty years of increasing use have testified

*Samples and Literature on request*

FELLOWS MEDICAL MFG. CO., Inc., 26 Christopher St., New York

# Keeping Faith—

The scientific principles on which *Antiphlogistine* was originally compounded, have always been the common property of the medical profession.

The faithfulness with which the original product has, for more than *twenty-five* years, been maintained, remains the proud stewardship of the original makers.

The unbiased reports of thousands of physicians, basing their opinion upon their experience with *Antiphlogistine* in both hospital and private practice, conclusively prove its dependable value in all inflammatory and congestive conditions.

*Antiphlogistine*

IS THE SAME TO-DAY AS IT  
WAS TWENTY-FIVE YEARS AGO.
